TRANSLATING RESEARCH INTO ACTION

JOB PLACEMENT AND DISPLACEMENT

Career counseling for young, college-educated job seekers in France helped them find work sooner, but this improvement came at the expense of jobs for those who did not receive counseling, and it did not translate into a long-term increase in employment rates.

Featuring an evaluation by Bruno Crépon, Esther Duflo, Marc Gurgand, Roland Rathelot, and Philippe Zamora

outh unemployment is a growing concern in many countries, including France where more than a quarter of recent graduates cannot find stable work. The governments of several developed countries are increasingly relying on specialized job-search counseling to help young graduates find their first jobs. By preparing job seekers for the recruitment process, and by connecting them with potential employers, counseling agencies are thought to both smooth the process of finding work and create a foundation for long-term employment.

However, it is possible that offering job counseling simply transfers job opportunities from individuals who do not receive counseling to those who do, creating a "displacement effect." If this is the case, then the net effect of job counseling programs on the employment rate could be negligible. Without empirically testing this policy, it is not possible to know the total effect of job counseling. How do intensive job counseling services affect employment rates among those who receive counseling and in the overall job market?

In a randomized evaluation, J-PAL affiliated professors Bruno Crépon (CREST), Esther Duflo (MIT), Marc Gurgand (PSE), Roland Rathelot (CREST), and Philippe Zamora (CREST) examined the short- and long-run impacts of job counseling among those who were, and were not, offered the program. Researchers randomly selected young, college-educated job seekers in 235 communities to receive intensive career counseling from a private agency that had been contracted by the government. The study also examined whether increasing the number of counseled individuals within a community displaced people who did not receive counseling for finding jobs.

- After eight months, individuals who were offered intensive counseling were 2.5 percentage points
 more likely to have obtained long-term employment than their peers in the same areas who did not
 receive this counseling. However, after twelve months, these gains disappeared.
- Providing intensive job counseling created a displacement effect. Although job seekers who were offered intensive counseling were 2.5 percentage points more likely to be employed in the short run than their peers who lived in the same communities but were not offered counseling, these peers were 2.1 percentage points less likely to have long-term employment than job seekers in areas where intensive counseling was not offered at all. Thus, overall, job seekers assigned to the treatment group had almost the same likelihood of finding long-term employment as those in areas where counseling was not offered at all.
- The low overall impact on employment rates for job seekers assigned to the treatment group is partly due to a relatively low take-up of the program. Only 35 percent of the treatment group actually enrolled in intensive counseling, so the positive impact for those who enrolled was partially offset by displacement effects among those in the treatment group who did not enroll.
- This displacement effect was strongest in contexts where job seekers eligible for counseling were competing for a limited number of jobs. Much of the displacement effect observed in this study was driven by displacement in communities where the job market was extremely competitive.

EVALUATION

rance has a large population of young, college-educated job seekers. An estimated 25–32 percent of university graduates are unable to find stable work three years after graduation. Some of these young graduates do not benefit from resources like unemployment benefits because they lack a sufficient employment history. In 2007, the Ministry of Labor began subcontracting job counseling services for young graduates to private agencies, which were believed to be more efficient in this sector than the French public employment agency, Pôle Emploi.

A randomized evaluation of this program was carried out from 2007 to 2010, covering 235 communities in ten regions throughout France. The goal of the evaluation was to assess whether offering job counseling created a displacement effect among job seekers who do not receive counseling, and how large this effect might be. Nearly 30,000 young, educated job seekers were randomly selected to be part of the evaluation. These youth were generally in their mid-twenties, college-educated (they possessed at least a two-year degree), and had not found stable work for at least six months. Nearly two-thirds of the sample consisted of women. Because the job seekers had spent very little time working, 67 percent were not receiving unemployment benefits at the time of the study.

The evaluation used a two-step randomization approach: first, randomly assigning the proportion of job seekers who would receive intensive counseling in a given community, and then randomly assigning job seekers in each treated community into the treatment or comparison group. Individuals assigned to the treatment group were put in contact with a private agency for intensive job counseling lasting a year, while those in the comparison group continued to have the option of receiving standard job counseling from Pôle Emploi. Since both treatment and comparison individuals were eligible to receive counseling through Pôle Emploi, this evaluation measures the impact of supplementing public employment counseling with more intensive counseling from a private provider.

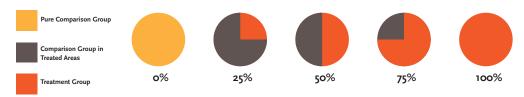

DETAILS OF THE INTERVENTION

Intensive job counseling with private firms

Private counseling firms (both for-profit and non-profit) received the names of job seekers and invited them to participate in a two-stage counseling program. The first stage focused on finding long-term employment (lasting at least six months) and the second focused on stabilizing them in their new job. The government did not prescribe a specific counseling structure, but it provided the agencies with incentives—up to $ext{eq}$, too per person counseled—for meeting specific outcome targets: enrolling an eligible job seeker in the program, finding that job seeker a job contract of at least six months, and having that job seeker still employed six months after entering the job.

Proportion of local job seekers receiving counseling Researchers varied the proportion of eligible youth who were offered counseling within each community from 0%, 25%, 50%, 75%, up to 100% (FIGURE 1) to examine the effects of having more or fewer people receiving counseling in a local job market. If job counseling for some displaces others from jobs, then one would expect to see higher unemployment among youth who were not offered counseling in communities where some youth received intensive counseling.

FIGURE 1: VARIATION IN PROPORTION OF PEOPLE TREATED, ACROSS COMMUNITIES

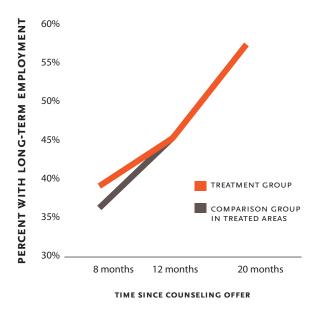

Researchers followed individuals in the treatment and comparison groups for almost two years, keeping track of whether or not they participated in intensive counseling, how many times they met with their counselor, what type of support they received, and their employment status.

Only 35 percent of the treatment group enrolled in the intensive counseling program. This low take-up may have been because nearly half of the participants already had some form of employment when they were assigned to receive counseling. Take-up of intensive counseling services was higher among people who were not working, had less advanced degrees, and were receiving government unemployment benefits.

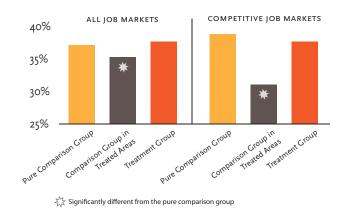

Individuals in the treatment group found work more quickly than those in the comparison group in the same areas, but these gains disappeared after twelve months. After eight months, job seekers in the treatment group were 2.5 percentage points more likely to have found long-term employment, an effect that was mostly driven by men. Increases in employment were also driven by job seekers who found fixed-term contracts, and there was no increase in permanent employment contracts. However, all employment gains disappeared after 12 months and individuals in the treatment group were no more likely to be employed than those in the comparison group (FIGURE 2).

FIGURE 2: RATES OF LONG-TERM EMPLOYMENT OVER TIME

Providing intensive job counseling created a displacement effect, lowering the employment rate among the comparison group individuals who lived in treatment areas. In treatment areas, job seekers who were offered counseling were 2.5 percentage points more likely to have found long-term employment after eight months than their peers who did not receive counseling. However, these peers were 2.1 percentage points less likely to have found long-term employment than job seekers in areas where no one received counseling. The net effect of being offered the program is, therefore, small and insignificant (Figure 3, left panel).

FIGURE 3: EMPLOYMENT RATES AMONG TREATED AND UNTREATED JOB SEEKERS

The low overall impact of being offered intensive counseling is partly due to the relatively low take-up of the program. Since only 35 percent of those offered intensive counseling chose to enroll, the direct benefit on those who took up the program was essentially compensated by the displacement effects on the job seekers who were assigned to the treatment group but did not enroll.

Displacement effects were strongest in places where job seekers eligible for the program were competing for a smaller pool of jobs. In treatment areas with extremely competitive job markets, the employment rate among the comparison group individuals was lower by 7.7 points than the employment rate in areas where no treatment was offered at all (FIGURE 3, right panel).

POLICY LESSONS

Intensive job counseling in France helped young graduates find work slightly faster than their peers who did not receive counseling in the same areas, but did not increase their employment rates in the long term. This evaluation found no evidence for the presence of a "stepping stone" effect, where a fixed duration job in the short run can lead to a permanent position.

Positive impacts for individuals who participate in a program do not necessarily indicate positive impacts for the population as a whole. Even if the beneficiaries of intensive job counseling are more likely to find employment, their success may come at the expense of other job seekers with whom they compete in the labor market. In programs that have low take-up, this displacement effect may be large enough to result in almost zero effect on beneficiaries as compared to others not affected by the program at all.

It is possible to empirically test large-scale labor market programs and generate evidence that can guide national policies. Most existing evaluations of active labor market policies compare treated and untreated workers within the same communities, ignoring possible spillover effects. Without a large-scale, market-level evaluation, this study would have concluded that intensive job counseling has a positive impact in the short run; it would not have been possible to know whether a displacement effect existed, and whether it outweighed the benefits to individuals who participated in the program.
