

Massachusetts Institute of Technology | Department of Economics

**Evaluating Social Programs
Executive Training at J-PAL**

May 30 – June 3, 2006
MIT, Room E51-376

Logistical Information

Address:

Room E51-376
Tang Center (Building E51)
MIT Sloan School of Management
70 Memorial Drive, Cambridge, MA 02139-4307

Directions:

by car — From I-90 east, take the Cambridge/Brighton exit 18. Follow the signs to Cambridge and cross the River Street Bridge. After the bridge, turn right onto Memorial Drive. Follow Memorial Drive past the BU and Harvard Bridges. After the Harvard Bridge (Massachusetts Ave.), take a left turn onto Wadsworth St. at the sign for Kendall Square. The Tang Center (E51) will be on your left.

From I-93, take exit 26, and follow the signs to Back Bay along Storrow Drive West, approximately 1.5 miles, to the exit for Route 2A. The exit will be on the left, just before the Harvard Bridge (also called the Massachusetts Ave. Bridge) take a right onto Memorial Drive. Turn left onto Wadsworth St. at the sign for Kendall Square. The Tang Center (E51) will be on your left.

by bus - The **CT2 (Cross Town)** stops at the Kendall Square T Station, as well as on the corner of Massachusetts Avenue and Vassar St., near the main MIT entrance. The **Route 1** or Dudley/Harvard Station bus stops at the main MIT entrance on Massachusetts Avenue and provides transportation to Central Square and Harvard Square.

by subway - By MBTA ("The T") train, take the **Red Line** to the Kendall/MIT Station. Once above ground (you will be on Main Street), head for the nearby Bank of America on the corner of Wadsworth Street. Turn right onto Wadsworth and continue walking half a block down the street toward the Charles River. Tang Center is located at the first corner at the right. Once inside the building, take the elevators, located to your right, to the third floor and follow the signs to the classrooms (the course will be held in room E51-376).

Parking:

- On-site parking, fee: \$8 hourly, \$20 daily
- Valet parking, fee: \$25 daily

Restaurants in the area:

Kendall Square

- **Au Bon Pain** (Cafe)
- **Character's Bar & Grill** (Marriott)
- **Florentina Restaurant** (Italian)
- **Kendall Hotel**
- **Kendall Market & Deli**
- **Legal Seafood**
- **Polcari's** (Italian)
- **Rebecca's Café**
- **Dunkin Donuts**

Massachusetts Avenue

- **All Asia**
- **Asgard Pub** (Irish bar and grill)
- **Chicago Pizza**
- **Desi Dhaba** (Indian)

Main Street

- **Bertucci's** (pizza, etc.)
- **Border India**
- **Cuchi Cuchi** (bar & tapas restaurant)
- **Royal East** (Chinese)
- **Stefani Pizzeria**

ATMs and Banks:

Cambridge Trust, Main Street at Kendall Square

Bank of America, Main Street at Kendall Square

Post Office:

Located on Main Street at Kendall Square

- **Fresco's Grill** (breakfast, subs)
- Luna Café
- **Miracle of Science** (bar & grill)
- **Pu Pu Hot Pot** (Chinese)
- **Royal India**
- **Sidney's** (at the Hotel @ MIT)
- **Thailand Café**
- **Toscanini's ice cream** (homemade ice cream)

What to bring to the course:

- Background information or short documents for your ideas on a possible evaluation
- A laptop (if you have one available) to help with your group project work

Massachusetts Institute of Technology | Department of Economics

Evaluating Social Programs

Executive Training at J-PAL

May 30 – June 3, 2006

MIT, Room E51-376

Course Schedule

Tuesday, May 30

8:30 AM – 9:15 AM	Continental Breakfast
9:15 AM – 9:30 AM	Welcome
9:30 AM – 11:00 AM	Lecture 1: What is Evaluation? <i>Lecturer: Abhijit Banerjee (MIT)</i>
11:00 AM – 12:00 PM	Group Discussion and Casework: Case 1 (Get Out the Vote)
12:00 PM – 1:30 PM	Lunch
1:30 PM – 3:00 PM	Lecture 2: Why Randomize? <i>Lecturer: Dan Levy (Harvard University)</i>
3:00 PM – 4:30 PM	Group Project Work (groups assigned; topics for presentation chosen) <i>TA available</i>
4:30 PM – 6:00 PM	Group Discussion and Casework: Case 2 (Balsakhi) <i>TA available</i>

Wednesday, May 31

8:00 AM – 10:30 AM	Continental Breakfast and Group Project Work/Casework Case 2 (Balsakhi) <i>TA available</i>
10:30 AM – 12:00 PM	Lecture 3: How to Randomize? Part I <i>Lecturer: Dean Karlan (Yale University)</i>
12:00 PM – 1:30 PM	Lunch

50 Memorial Drive • E52-243C • Cambridge, MA 02142

Phone: 617 324 0108 • Fax: 617 253 1330 • Email: povertyactionlab@mit.edu • www.povertyactionlab.org

1:30 PM – 3:00 PM	Lecture 4: How to Randomize? Part II <i>Lecturer: Rachel Glennerster (J-PAL)</i>
3:00 PM – 4:30 PM	Group Project Work <i>TA available</i>
4:30 PM – 6:00 PM	Group Discussion and Casework: Case 3 (Panchayats) <i>TA available</i>

Thursday, June 1

8:00 AM – 10:30 AM	Continental Breakfast and Group Project Work/Casework: Case 3 (Panchayats) <i>TA available</i>
10:30 AM – 12:00 PM	Lecture 5: Measurement and Outcomes <i>Lecturer: Esther Duflo (MIT)</i>
12:00 PM – 1:30 PM	Lunch
1:30 PM – 3:00 PM	Lecture 6: Sample Size and Data Management <i>Lecturer: Esther Duflo (MIT)</i>
3:00 PM – 4:30 PM	Group Project Work <i>TA available</i>
4:30 PM – 6:00 PM	Group Discussion and Casework: Case 4 (Deworming) <i>TA available</i>
6:00 PM – 8:00 PM	Group Dinner

Friday, June 2

8:00 AM – 10:30 AM	Continental Breakfast and Group Project Work/Casework: Case 4 (Deworming) <i>TA available</i>
10:30 AM – 12:00 PM	Lecture 7: Managing Threats <i>Lecturer: Michael Kremer (Harvard University)</i>
12:00 PM – 1:00 PM	Lunch
1:00 PM – 2:30 PM	Lecture 8: Analyzing Data <i>Lecturer: Abhijit Banerjee (MIT)</i>
2:30 PM – 6:00 PM	Finalize Group Project Presentation <i>TA available</i>

Saturday, June 3

8:00 AM – 9:00 AM	Continental Breakfast
9:00 AM – 10:00 AM	Lecture 9: Wrap-up and Policy Impact <i>Lecturer: Rachel Glennerster (J-PAL)</i>
10:00 AM – 12:15 PM	Group Presentations
12:15 PM – 1:15 PM	Lunch
1:15 PM – 3:30 PM	Group Presentations
3:30 PM – 4:00 PM	Closing Remarks

Massachusetts Institute of Technology | Department of Economics

**Evaluating Social Programs
Executive Training at J-PAL**

May 30 – June 3, 2006

MIT, Room E51-376

Course Lecturers

Abhijit Banerjee

Abhijit Banerjee is the Ford Foundation Professor of Economics in the Department of Economics at MIT, a co-founder and Director of the Abdul Latif Jameel Poverty Action Lab, and past President of the Bureau for Research and Economic Analysis of Development (BREAD). He received his Ph.D. in economics from Harvard University in 1988, and taught at Princeton and Harvard before joining the MIT faculty in 1996. In 2001, he was the recipient of the Malcolm Adeshesiah Award, and was awarded the Mahalanobis Memorial Medal in 2000. He is a fellow of the American Academy of Arts and Science and a member of the Council of the Econometric Society, and has been a Guggenheim Fellow and Alfred P. Sloan Research Fellow. His areas of research are development economics, the economics of financial markets, and the macroeconomics of developing countries.

Esther Duflo

Esther Duflo is the Abdul Latif Jameel Professor of Poverty Alleviation and Development Economics in the Department of Economics at the Massachusetts Institute of Technology. She is a co-founder and director of the Abdul Latif Jameel Poverty Action Lab, Research Associate at the National Bureau for Economic Research, and on the board of directors of the Bureau for Research and Economic Analysis of Development (BREAD). She received her undergraduate degree in history and economics from the Ecole Normale Supérieure (Paris) in 1994, a master's in economics from DELTA (Paris) in 1995, and her Ph.D. in economics from MIT in 1999. She is the recipient of the Bronze Medal from the Centre National de la Recherche Scientifique (2005), Le Monde's Cercle des économistes Best Young French Economist Prize (2005), and the Elaine Bennett Prize for Research (2003). She is co-editor of the *Journal of Development Economics* and associate editor of the *Journal of Economic Perspectives*. Duflo specializes in development economics and the design and evaluation of effective anti-poverty policy. She has studied household behavior, educational choice and returns to education, decentralization, industrial organization in developing countries, and credit constraints.

Rachel Glennerster

Rachel Glennerster joined the Abdul Latif Jameel Poverty Action Lab at MIT as Executive Director in 2004. She earned her B.A. in Philosophy, Politics, and Economics from Oxford University and her Ph.D. in Economics from the University of London. She was an Economic Advisor at the UK Treasury and Development Associate at the Harvard Institute for International Development. She acted as Technical Assistant to the UK Executive Director of the IMF and World Bank focusing on loans to Russia and the former Soviet Union before joining the IMF staff in 1997. At the IMF she assisted countries affected by the Kosovo crisis, helped negotiate a major debt relief package for Mozambique, and helped design and implement reforms to the International Financial System in the aftermath of the Asian Financial Crisis. She is coauthor of *Strong Medicine: Creating Incentives for Pharmaceutical Research on Neglected Diseases*.

Dean Karlan

Dean Karlan is Assistant Professor of Economics at Yale University. Prior to joining Yale, he was Assistant Professor of Economics and International Affairs at Princeton University. He is President of Innovations for Poverty Action, a Research Fellow at the Abdul Latif Jameel Poverty Action Lab, and an Affiliate of BREAD. He also holds an M.B.A. and an M.P.P. from the University of Chicago and a B.A. in International Affairs from the University of Virginia. Dr. Karlan received his Ph.D. in Economics from M.I.T. He has consulted for the World Bank, the Asian Development Bank, and FINCA International. He participates in a working group at CGAP on Savings Mobilization. His research focuses on the use of field experiment to learn what social policies work, what do not, and why. Most of his work is based on examining the efficacy of various microfinance programs based on their impact on clients and households. His other research covers fundraising, voting, education and behavioral economics.

Michael Kremer

Michael Kremer is a J-PAL affiliate, the Gates Professor of Developing Societies in the Department of Economics at Harvard University and Senior Fellow at the Brookings Institution. He is a Fellow of the American Academy of Arts and Sciences, a recipient of a MacArthur Fellowship and Harvard Presidential Faculty Fellowship, and was named a Young Global Leader by the World Economic Forum. Kremer's recent research examines education and health in developing countries, immigration, and globalization. He and Rachel Glennerster have recently published *Strong Medicine: Creating Incentives for Pharmaceutical Research on Neglected Diseases*. His articles have been published in journals including the *American Economic Review*, *Econometrica*, and the *Quarterly Journal of Economics*. Kremer previously served as a teacher in Kenya. He founded and was the first executive director of WorldTeach, a non-profit organization which places 360 volunteer teachers annually in developing countries.

Dan Levy

Dan Levy is Visiting Assistant Professor at Harvard University's John F. Kennedy School of Government, and Director of Training at the Abdul Latif Jameel Poverty Action Lab. He has served as a Senior Researcher at Mathematica Policy Research, where he has been involved in the evaluation of several social programs. His teaching focuses on quantitative methods and program evaluation. His research interests lie in the general area of social policy. He currently serves as the Deputy Project Director of the evaluation of the PATH program, a conditional cash transfer program in Jamaica. He has been involved in the evaluation of an after-school program, a methodological review of studies comparing the use of random assignment and quasi-experimental methods to estimate program impacts, and a technical assistance project with Mexico's Social Development Ministry (Sedesol). He has also served as a Research Affiliate of the Joint Center for Poverty Research, an Adjunct Faculty Member at Georgetown Public Policy Institute, and a consultant at the World Bank. He received his Ph.D. in Economics from Northwestern University and his B.A. from Universidad Metropolitana (Caracas, Venezuela). He is fluent in Spanish and French.

Evaluating Social Programs
Executive Training at the Poverty Action Lab
March 21–25, 2005

Group Work Instructions

You will be assigned to groups of 5 people. We will do our best to ensure that each group includes participants with a range of different experiences but some common areas of interest. You will carry out two types of activities within these groups:

- i) casework and discussions;
- ii) preparation of group proposal.

Casework and Discussions

Each case covers a specific set of topics which are the subject for the lectures for each day of the course. The cases provide background on one (or in some cases two) specific evaluations which will be referred to in the lectures. In addition, each case includes discussion topics designed to get you thinking about the issues before the lectures. Some of the cases also include exercises for you to complete. You will be provided with Excel files containing these exercises at the start of the “group work” sessions. You will be expected to read the relevant case, go through the discussion topics, and complete the exercises before the related lecture on the case.

Group Proposal

Each group will—throughout the week—work on a proposal for an evaluation on a topic of their choice. Different aspects of evaluation will be covered in the lectures and the casework, and these should be reflected in the group proposal. On Friday, each group will present their proposal and receive comments from the other participants and the lecturers. This is an ideal time to get feedback on an evaluation you may be planning.

The outputs for the project will be:

- i) a 20-minute presentation (with an additional 10 minutes for questions and feedback);
- ii) a 3-4 page note summarizing the proposal.

Both the presentation and the note should cover the following issues:

- i) the objective and rationale of the evaluation—what is the question you are asking and why is it important or interesting?
- ii) randomization design—how will the treatment and control groups be determined, and at what level will the randomization take place?
- iii) measurement issues—how will you measure whether the program is a success? On what variables will data be collected? How will it be collected? In addition to final outcome measures, will you be collecting data on the mechanism by which the program works? If so, what data will you collect on this?
- iv) What magnitude of effect will you be trying to detect? What is the sample size you will be using? Why is this the right sample size?
- v) What are the risks to the integrity of the evaluation? How will you seek to minimize these?
- vi) How will the data be analyzed?
- vii) To what use will you put the results? How will the results impact future policy/programs?

Case 1: Get Out the Vote **Phone Calls to Encourage Voting:** **Do they “work”?**

This case study is based on “Comparing Experimental and Matching Methods using a Large-Scale Field Experiment on Voter Mobilization,” by Kevin Arceneaux, Alan S. Gerber, and Donald P. Green, *Political Analysis* 14: 1-36. We thank the authors for allowing us to use their paper and for sharing their data with us.

Introduction

Hello, may I speak with Joe Iowa please? Hi. This is Marc Shotland calling from Vote 2002, a non-partisan effort working to encourage citizens to vote. We just wanted to remind you that elections are being held this Tuesday. The success of our democracy depends on whether we exercise our right to vote or not, so we hope you'll come out and vote this Tuesday. Can I count on you to vote next Tuesday?

In the week preceding the 2002 U.S. congressional elections, volunteers for the Vote 2002 Campaign, launched a voter mobilization drive. During this week, they called 60,000 potential voters and gave the preceding message.

Did the Vote 2002 Campaign increase the voter turnout rate? How would we find out? This case study tackles these questions by examining different methods people may use to evaluate the effect of a program or intervention. While the context of this case study is electoral politics in the U.S., the issues that arise here are also present when evaluating the effect of social programs in the context of developing countries.

I - Background

Historical Voter Turnout in the US

The United States has seen wide variations in the percent of the population that participates in elections (known as voter turnout). Much of this variation is the result of laws that changed who was eligible to vote. In 1868, after the Civil War, citizenship was extended to “all persons born or naturalized in the United States.”¹ The right to vote, regardless of “race, color or previous condition of servitude,” soon followed with the passage of the 15th Amendment.² These new constitutional amendments resulted in nearly one million recently-freed slaves registering to vote.³ Women won the right to vote in 1920 with the 19th Amendment to the Constitution.⁴ And in 1965, obstacles erected to prevent certain populations from voting were deemed illegal by the Voting Rights Act.⁵ Since then, voter turnout has gradually declined, suggesting a growing apathy towards the democratic process.⁶

International Voter Turnout

~Voter Turnout in other Democracies~

The decay in voter interest is a concern for many countries. In the more developed countries, voter turnout has been declining in the past half century. Figure 1, below, shows the trend in voter turnout for a number of regions since 1950.⁷

Figure 1

Voter Mobilization Drives

In the 1998 and 2000 U.S. congressional elections, voter turnout was particularly low. Among the Voting Age Population (VAP) in the U.S., only 46.6% voted in the 2000 congressional (and corresponding presidential) elections and a record-low 34.7% voted in 1998, the prior mid-term election.⁷ With another mid-term election approaching in 2002, individuals in Iowa and Michigan, concerned with the downward trend in participation, organized to launch the Vote 2002 campaign—a telephone drive reminding voters of the election date and encouraging them to vote. With enough volunteers, and by contacting enough potential voters, they expected to dramatically improve voter turnout in their respective states.

There is some debate, however, over whether telephone campaigns are actually effective. In the past 40 years of voter mobilization, the traditional, person-to-person campaign tactics such as canvassing have been replaced by mass marketing techniques like direct mail and telephone calls.⁸ This period has seen a decline in the number of political party volunteers as well as membership in nonpartisan organizations such as the Lions, Rotary and Kiwanis Clubs. Alan Gerber and Donald Green, in a study conducted in 2000, contend that “a decline of personal mobilization has arguably contributed to the erosion of voter turnout in the United states since the 1960s.”⁹ This contention seems reasonably convincing. The correlation between the rise of telephone campaigning and the decline in voter turnout, however, does not mean that the telephone campaign *caused* the decline in voter turnout. It is possible that had canvassing been replaced by *nothing* as opposed to telephone calls and direct mail, even fewer people would be voting than currently are. So does mass marketing at least slow the decline? The next section explores whether this was indeed the case by asking the more specific question of whether the Vote 2002 Campaign had an effect on voter turnout.

II – Did the Vote 2002 Campaign work?

Vote 2002 members obtained the telephone numbers of 60,000 individuals. They called all 60,000, but were able to speak with only about 25,000. For each individual, they recorded whether or not the call was completed successfully. They also collected data on household size, age, gender, whether the voter was newly registered, which state and district the voter was from, and the competitiveness of that district. And from official voting records, they were able to determine whether these individual households actually voted in the 2002 election.

Discussion Topic I: Analyzing 2002 Data

Vote 2002 has agreed to share its data with you on the 60,000 households in their campaign. You are asked to use these data to estimate the impact of the Vote 2002 campaign on voter participation. You are asked to consider the two methods described below. You may want to refer to the appendix for some background on estimating the impact of a program.

Method 1 – Difference in proportion of voters between reached and not-reached

Assume the 25,000 households who received the call constitute the participant group and the other 35,000 households (who were called but not reached) represent the comparison group. If you want to see what the impact of receiving a call has on voter turnout, you could check whether those who received the call were more likely to vote than those who did not receive the call. Compare the proportion of people who voted in the treatment group and that of the comparison group.

Discussion question 1 – What might the problem be in using this method to evaluate the effect of the program? Would it give you an accurate measure of the true impact?

Method 2 – Use multiple regression to control for differences between reached and not-reached

If you were concerned that people reached might have different inherent characteristics from those who were not reached, you could control for these differences by using a multivariable regression as follows: The participant and comparison groups are defined in the same way as in method 1. To estimate the impact of the program, you run a regression where the “dependent variable” is a zero/one variable indicating whether the person voted or not (i.e. 0 = did not vote, 1 = voted). The “key explanatory variable” is a zero/one variable indicating whether the person received the call or not (i.e. 0 = did not receive the call, 1 = received a call). Potential differences in characteristics can be controlled for using other “explanatory variables” such as age, gender, newly registered voter, etc. The coefficient on the key explanatory variable (i.e. received the call) represents the estimated impact of the program.

Table 1 presents the estimated impact of the Vote 2002 Campaign using each of these methods. Table 2 compares the average characteristics of the participant and comparison groups used in both of these methods.

Discussion question 2 – For method 2, discuss whether it is reasonable to expect that the estimated impact represents the true causal effect of Vote 2002 on voter participation.

Discussion question 3 – Why do you think the estimated impact using method 2 was lower than the estimated impact using method 1?

Discussion question 4 – Can you address the weaknesses of method 1 by taking a random sample from the participant group and a random sample from the comparison group?

Discussion question 5 – Using the data described above, can you think of more convincing methods to estimate the impact of the Vote 2002 campaign?

Table 1: Percent who voted, Reached and Not-Reached			
	Voter turnout of voters who were:		
	Reached	Not Reached	Estimated Impact
Method 1:			
Simple Difference	64.5%	53.6%	10.8 pp*
Method 2:			
Multiple Regression ^a			6.1 pp*

pp=percentage points

*: statistically significant at the 5% level

^a: controls include household size, age, newly registered, county, state senate district, state house district, from a competitive district

Table 2: Characteristics of Reached and Not-Reached Groups			
	Reached	Not Reached	Difference
Household Size	1.56	1.50	0.06
Average age	55.8	51.0	4.8
Percent female	56.2%	53.8%	2.4 pp*
Percent newly registered	7.3%	9.6%	-2.3 pp*
Percent from a competitive district	50.3%	49.8%	0.5 pp
Percent from Iowa	54.7%	46.7%	8.0 pp*
Sample Size	25,043	34,929	

pp=percentage points

*: statistically significant at the 5% level

Discussion Topic II: Using Panel Data

If you are still concerned about differences in characteristics between reached and non-reached individuals, you could use panel data – i.e. track the same person over time.

It turns out that staff members of the Vote 2002 also had data on whether the person voted in the previous elections (1998 and 2000). Past voting behavior is thought to be a strong predictor of future voting behavior. Table 3 indicates past voting behavior for the group of people who were reached by the Vote 2002 Campaign and the group of people who were called but not reached.

Discussion question 1 - How can these data on past voting behavior be used to improve your analysis?

Discussion question 2 – Given the information on Table 3, would you expect the method you proposed in the previous question to result in a higher or lower estimate of the impact of the Vote 2002 Campaign on voter turnout?

Table 3: Percent who voted in past elections of Reached and Not-Reached Groups			
	Voter turnout in 1998 and 2000 of voters who, in 2002, were:		Difference
	Reached	Not Reached	
Voted in 2000	71.7%	63.3%	8.3 pp*
Voted in 1998	46.6%	37.6%	9.0 pp*

pp=percentage points

*: statistically significant at the 5% level

Discussion Topic III: Matching

It turns out that staff members from the Vote 2002 Campaign also have similar data on about 2,000,000 individuals living in the same states where the 60,000 individuals called by the Vote 2002 Campaign lived. One way to estimate the impact of the Vote 2002 campaign is to select as a comparison group a subset of the non-reached individuals (i.e. the 2,000,000 individuals not called + 35,000 individuals called but not reached) who look similar to the participant group (i.e. the 25,000 called and reached).

To select this subset, researchers often employ a statistical procedure called matching. While there are many ways to do matching, it turns out that in this context it is possible to do “exact matching” for almost all the individuals in the sample, i.e. for each of the 25,000 individuals we can select another individual who has the exact same characteristics (i.e. age, gender, etc). In this way, the participant and comparison group will have exactly the same observable characteristics. An illustration of exact matching is presented in Figure 2.

Matching was performed and then the impact of the Vote 2002 campaign was estimated by taking the difference between the voter turnout rate in the participant group and the voter turnout rate in the comparison group (i.e. the “matched” group). Table 4 presents the results.

Discussion question – Assess whether it is reasonable to expect that the impact estimated using this method represents the true causal effect of Vote 2002 on voter participation.

Figure 2 – Illustration of Exact Matching

Treated Subjects				Untreated Subjects			
Age	Gender	Precinct	Previous Vote	Age	Gender	Precinct	Previous Vote
30	1	10	1	55	1	16	0
45	0	15	1	45	0	15	1
19	0	12	0	19	0	12	1
32	1	16	1	56	1	14	0
55	1	16	0	28	1	12	0
42	0	15	1	18	1	12	0
70	1	10	0	19	0	12	0
24	1	12	0	21	0	14	1
21	0	14	1	21	0	14	1
34	1	14	0	25	0	10	1
62	0	10	0	62	0	10	1

Source: Arceneaux, Gerber, and Green (2004)

Table 4: Matching Analysis			
	Voter turnout of voters who:		Estimated Impact
	Were reached	Had matching characteristics but were not reached	
Method 3a: Matching on four covariates^a	64.5%	60.8%	3.7 pp*
Method 3b: Matching on six covariates^b	64.5%	61.5%	3.0 pp*
Method 3c: Matching on all covariates^c	65.9%	63.2%	2.8 pp*

pp=percentage points

*: statistically significant at the 5% level

^a Four covariates included: household size, age, newly registered, state

^b Six covariates included: household size, age, newly registered, state, from a competitive district, voted in 2000.

^c All covariates included: household size, age, newly registered, county, state senate district, state house district, from a competitive district, voted in 2000, voted in 1998. Using all covariates, only 90% of the reached-individuals had exact matches in the comparison group.

Discussion Topic IV: Randomized Experiment

It turns out that the 60,000 individuals were *randomly* selected from the larger population of about 2 million potential voters. This is akin to the randomization that occurs in a clinical trial, where the treatment/drug is randomly assigned to be received by one group of patients but not the other. We can exploit this randomization to estimate the impact of the Vote 2002 campaign. The idea is that the 60,000 individuals Vote 2002 called (now called the treatment group) should be identical to the 2,000,000 individuals (now called the control group) in everything (observable and unobservable) except for the fact that the first group was called by the Vote 2002 Campaign. Table 5 compares the treatment and control groups along some observable characteristics. Table 6 presents the estimated impact of the Vote 2002 Campaign by comparing the voter turnout of the treatment group with the voter turnout of the control group.

Discussion question 1 – Notice that the two groups look very similar in Table 5. Is this what you would expect?

Discussion question 2 – Notice that the impact estimates in Table 6 are not statistically significant. This result is different than those obtained with the previous methods. What may be the rationale behind this difference in results?

Technical note: For reasons we will discuss later in the course, the impact estimate from taking this simple difference needs to be adjusted to take into account the fact that 35,000 individuals in the treatment group were not reached. Table 6 shows both the simple comparison of treatment and control groups—where treatment is all those Vote 2002 called. It also shows the implied impact of the program after an adjustment is made for the fact that not all of this group were reached. (You will learn how to do this adjustment in the course).

Table 5: Characteristics of Treatment and Control Groups (In Michigan's Competitive Districts)^a			
	Treatment	Control	Difference
Voted in 2000	56.7%	56.4%	0.4 pp
Voted in 1998	22.7%	23.1%	-0.5 pp
Household Size	1.50	1.50	0.00
Average age	52.0	52.2	-0.2
Percent female	54.6%	55.2%	-0.6 pp
Percent newly registered	11.6%	11.7%	0.0 pp
Sample Size	14,972	1,153,072	

pp=percentage points

*: statistically significant at the 5% level

^a Before treatment households were randomly selected, the population was stratified by state and competitiveness (creating 4 distinct strata). This table presents the characteristics in the most populous stratum. Characteristics of treatment and control groups are similarly insignificant in the 3 other strata.

Table 6: Randomized Analysis			
	Voter turnout of voters who are in the:		Estimated Impact ^a
	Treatment Group	Control Group	
Method 4a: Randomized Simple Difference	58.2%	58.0%	0.2 pp
Method 4b: Randomized Multiple Regression			0.2 pp
Method 4c: Randomized IV (Adjusted) Regression			0.4 pp

pp=percentage points

*: statistically significant at the 5% level

^a The impact estimate is adjusted to measure the “treatment on the treated” only in Method 4c.

Conclusion

Table 7 presents impact estimates of the Vote 2002 Campaign using the different methods discussed in this case study.

Table 7 - Summary Table of Impact Estimates	
Method	Estimated Impact of the Vote 2002 Campaign
Simple Difference	10.8 pp*
Multiple Regression	6.1 pp*
Multiple Regression with Panel Data	4.5 pp*
Matching (All Covariates)	2.8 pp*
Randomized Experiment (IV)^a	0.4 pp

pp=percentage points

*: statistically significant at the 5% level

^a The estimated impact on those reached after adjustment for the fact that not all those randomly selected for the program were actually reached

As you can see, not all methods give the same result. Hence, the choice of the appropriate method is crucial. The purpose of this case study was not to evaluate one particular voter mobilization campaign, but to evaluate evaluation methods in this particular context.

In the analysis of the Vote 2002 campaign, we found that people who happened to pick up the phone were more likely to vote in the upcoming (and previous) elections. Even though we statistically accounted for some observable characteristics, including demographics and past voting behavior, there were still some inherent, unobservable differences between the two groups, independent of the get-out-the-vote campaign. Therefore, when our non-randomized methods demonstrated a positive, significant impact, this result was due to “selection bias” (in this case, selection of those who pick up the phone) rather than a successful get-out-the-vote campaign.

Discussion Topic V: Application to Development

Selection bias is a problem that arises in many program evaluations. Think about some of the non-randomized development programs you have, or have seen, evaluated. Discuss how the participant group was selected, and how “selection” may have affected the ability to estimate the true impact of the program.

Appendix – Estimating the impact (or causal effect) of the program

- Estimating a causal effect (a.k.a impact) of a program or intervention involves a comparison between the outcome had the intervention been introduced and the outcome had the intervention not been introduced. The latter is usually referred to as the *counterfactual*
- The *counterfactual* represents the state of the world that program participants would have experienced in the absence of the program (i.e. had they not participated in the program)
 - The counterfactual does not represent the state of the world in which participants receive absolutely no services, but rather the state of the world in which participants receive whatever services they would have received had they not participated in the program being evaluated
- The counterfactual can never be directly observed
 - Hence, the main goal of an impact evaluation can be viewed as an effort to *construct* or *mimic* the counterfactual
 - This is usually done by selecting a group of individuals that did not participate in the program
 - This group is usually referred to as the *control group* (in case of a randomized experiment) or *comparison group* (in case we are using non-experimental methods to estimate the impact)
 - How this group is selected is a key decision in the design of any impact evaluation
 - The idea is to select a group that is exactly like the group of participants in all ways except one: their exposure to the program being evaluated
 - The goal in the end is to be able to attribute differences in outcomes between the group of participants and the control/comparison group to the program (and not to other factors)

Case 2 – Remedial Education in India: A Randomized Evaluation of the “Balsakhi Program”

This case study, with kind permission of the authors, is based on “Remedying Education: Evidence from Two Randomized Experiments in India” (by Abhijit Banerjee, Shawn Cole, Esther Duflo, and Leigh Linden) (Poverty Action Lab Working Paper, 2004)

Introduction

At the United Nations Millennium Summit in September 2000, world leaders declared an ambitious set of objectives under the heading of the Millennium Development Goals. Included in the group of eight targets was universal primary education by 2015. While progress is being made towards this important goal, getting students in school is only the beginning. Poor infrastructure, high teacher absenteeism, limited inputs, and large class sizes reduce the quality of education received, especially by poor and under-qualified students. A study in India found that, of all third and fourth graders in Mumbai public schools, 25% cannot recognize letters and 35% do not recognize basic numbers.

UN reports have singled out both sub-Saharan Africa and South Asia as areas lagging in progress in their educational goals. In both these regions, though access to primary schooling has indeed increased, schools are often overcrowded and lack the resources necessary to effectively educate students. A simple comparison of pupil to teacher ratios from 2000 illustrates the gravity of the problem:

Region or Country	Pupil Teacher Ratio
G7 nations	16.4
Sub Saharan Africa	45.0 (2001)
--Kenya	30.0
South Asia	42.0 (1999)
--India	40.0
<i>(Source: World Development Indicators 2004)</i>	

Embedded in the problem of large classroom sizes is the high variation in student achievement levels within the same class. Lower performing students require different instruction tailored to their specific needs, and in large classrooms, a teacher cannot effectively instruct the mixed student population. Given the opportunity and resources to divide classrooms into smaller units, one possible way to address the educational needs of lower performing students is to stream these students into a particular class in which the teacher will be fully available to focus on them.

The difficulty of providing good education is further compounded by teacher absenteeism and lack of accountability to local officials due to their protected status as civil servants and state government employees. A recent World Bank-funded random survey of 200 schools found no teaching activity in half of the sample of 200 Indian primary schools (WDR 2004). There are also problems with the centralized hiring of teachers as public servants in developing countries. The guaranteed wages and benefits of public servants add a significant burden to government's budgets, and in low and middle income countries, teacher salaries amount to 80-90% of primary education spending (WDR, 2004). The push towards universal primary education combined with already strained budgets has created a crisis in providing an adequate number of trained teachers.

Use of Contract Teachers

This teacher supply problem has led researchers to examine programs involving the decentralized hiring of contract teachers. In the broadest sense, contract teachers are teachers who often (but not always) lack the full qualifications of an official government teacher, but who nonetheless meet a certain set of educational requirements and have usually undergone some training. Instead of being hired by the government as public servants, they are usually hired locally by NGOs or village governments on a contract basis.

This structure creates greater accountability for the contract teachers since the hiring, firing, and renewal decisions are not bound by government service rules. Contract teachers may be in charge of their own class, or they may work in tandem with a regular teacher and provide remedial or supplementary instruction. Generally, contract teachers receive no benefits, and their salary is dependent on their specific role. For example, contract teachers in Cambodia in charge of their own classes received pay equal to regular teachers while in Kenya, contract teachers receive roughly one quarter of a regular teacher's salary and *no* benefits. In India, contract teachers' salaries vary considerably:

Type of teacher	Monthly salary
Regular teacher	Rs 5,000
Contract teacher in charge of own class	Rs 900 - Rs 3,000
Contract teacher working part time alongside regular teacher	Rs 200 – 1,000
<i>(Source: Para Teachers, DPEP Calling)</i>	

The savings from the much-reduced salary free up resources that can be used to deal with high pupil teacher ratios and variation in student achievement. In addition, the decentralized hiring provides local communities with the chance to monitor the attendance and instruction of contract teachers and reward or penalize appropriately.

However, programs involving contract teachers are not without their critics. Some critics point to the lower qualifications, training, or experience of contract teachers as indicators that students in these classes will receive poorer instruction. There is also the possibility of gaming in assignment of government teachers as a result of contract teacher programs. The Cambodian program produced some widely publicized scandals involving preferential placement of official teachers into better locations with contract teachers filling in the deficit at the undesirable posts. Others point to possible interschool tensions between contract teachers and official teachers, with contract teachers resentful of their lower pay and official teachers fearful of replacement by the cheaper contract teachers.

All of these issues must be kept in mind and examined in any study of the effectiveness of using contract teachers in the developing world. In particular we need be concerned about how the overall system adjusts to the presence of these teachers. However, in areas

that are facing teacher shortages and very high pupil teacher ratios, contract teachers may have a lot to offer.

The Balsakhi Program: An Example from India

In the past 50 years or so, India has made impressive gains in its education system. The number of schools has grown from 223,600 in 1950 to 840,000 in 2004, enrollment has increased from 22.3 million to 155.7 million, and literacy has jumped from 16.6% to 65.4%. Despite these remarkable gains, there are still an estimated 42 million school-age children out of school. Furthermore, 40% of children enrolling in grade one drop out within five years of schooling (Govinda 2004). Achievement levels, based on testing of basic skills, are equally unimpressive for a significant portion of pupils.

Pratham, a Mumbai-based NGO, with the stated goal “Every child in school...and learning well”, has experimented with different models to improve education in India. In particular, the Balsakhi Remedial Education Program has great potential due to both its ease to replicate and its low cost (roughly \$5 per child per year). Pratham’s decision to expand the Balsakhi program in Vadodara and Mumbai in 2000 presented an opportunity to evaluate the program’s effect on student performance with a randomized design.

Presence of Pratham

With support from UNICEF, Pratham was established in Mumbai in 1994 and has since expanded to 39 cities/rural areas in 12 Indian states. As of 2002, Pratham’s network of 10,000 workers designed, implemented, and managed programs reaching over 220,000 children. Pratham has established a unique partnership among corporate leaders, government, and Indian communities in which innovative programs implemented by community volunteers and workers enhance education in municipal schools.

The Balsakhi Program

Pratham developed one of its core programs, the Balsakhi Remedial Education Program, in Mumbai in 1994 (expanded to Vadodara in 1999) in response to evidence that a high percentage of children in grades four and five in government schools lacked basic literacy and numeracy skills. In most parts of India, schools have automatic promotions which allow children to advance up to as high as the fourth grade without having to master any of the requisite skills associated with the first four grades. Students who have fallen behind tend to lose interest and drop out or get forced out because the teachers do not want them in class. They also make it harder for other children to learn, since the teacher needs to devote time to remedial lessons.

Literally translated as “friend of child”, the “balsakhi” is someone from the local community who has at least completed grade 12. This person is generally female, given

the relatively large number of available women with the skills and desire to enter the program. Based on the teacher's aid model in Western schools, the balsakhi for a particular grade works closely for two hours each day (out of a four hour school day) with groups of 15-20 weaker students *chosen by the school's instructor*. Since there are both morning and afternoon school sessions, she works with two different groups every day for a total of four hours. Pratham has developed a standardized curriculum and provides an initial two-week training session before the school year as well as ongoing support throughout the year. Pratham is also in charge of hiring and monitoring the balsakhis.

Pratham identifies the following features as key to the design of the Balsakhi program.

- In a small class, the balsakhi can provide more individualized attention, and as a member of the local community, the balsakhi is more familiar with and socially linked to the children.
- Removing children from the classroom benefits non-targeted children by reducing the effective student teacher ratio and by allowing the school instructor to proceed to more advanced topics.
- An effective balsakhi will eventually allow targeted children to return to the mainstream classroom with reinforced basic literacy and numeracy skills.
- The program is easily replicated. Balsakhis are paid roughly \$10/month, are recruited locally, and require relatively little training. Balsakhis also adapt to local space constraints, so there is low overhead and capital costs.
- The balsakhi turnover rate is high (on average a one year stay), so it is unlikely that the program's success depends largely on the ability of a few enthusiastic individuals.
- There is existing evidence that official teachers appreciate the extra help from the balsakhi in reducing class size and helping out with some other basic administrative tasks at the school. Furthermore, because of the high turnover rate and relatively low level of training, there is little threat that they will take over the official teacher's job.

Outcome Measures: Attendance and Test Scores

Researchers expected two possible effects of the balsakhi program on schooling: improved attendance and increased test scores. Removing remedial students for part of the day has two potential effects: (1) Lower achieving students are given closer, individualized attention from a local village resident and (2) Non-balsakhi taught students benefit from a smaller class size for a portion of the day and the ability of teachers to focus on more advanced material, thereby encouraging attendance of higher achieving students.

To test for any educational benefit from the balsakhi in the Vadodara sample, Pratham developed a two-part exam that tested math and language skills separately. This exam covered different skills that the Vadodara Municipal Corporation designated as "compulsory" for each of the grade levels. For example, the math skills test covered topics ranging from basic number recognition, counting, and ordering of single and double-digit numbers to basic addition and word problems. Similar exams were administered in Mumbai.

A Comparison to Kenya

Part I: Background of the Kenyan Extra Teacher Program

Akin to India, Kenya faces many of the same constraints in its attempts to achieve universal primary education. There are problems with teacher incentives, costs of educational inputs, overcrowded schools, and low achievement and completion rates. A recent study of Western Kenya found that teachers have absenteeism rates of nearly twenty percent (Glewwe et al, 2003). A 1996 study found primary school completion rates for students who enrolled in the first grade to be 43.3% for girls and 45.1% for boys (Abagi 1997). A 1998 study found that, on average, 4 primary school pupils share one text book (Abagi 1998).

These pre-existing problems have all been exacerbated by the 2003 reintroduction of free universal primary education. With the announcement of the new government policy, enrollment jumped from 6 million to roughly 7.2 million pupils, increasing pupil teacher ratios from 32:1 to 40:1 nearly overnight (Riddell 2003). The Kenyan National Union of Teachers estimates that the country needs an additional 60,000 primary school teachers in addition the existing 175,000, and the country faces a funding crisis (Wax 2003). Even prior to the universal primary education initiative, education accounted for 29% of Kenya's recurrent expenditure with 55% allocated to primary education and 93% of this used for teacher salaries (Riddell 2003).

Facing overcrowded schools and the inability of the central Kenyan government to provide more teachers, some communities and NGOs have explored contract teachers as a cost-effective means to improve education. As opposed to the civil servants hired by the Ministry of Education (MoE), contract teachers are hired locally by school committees. These contract teachers often have the same qualifications as the civil servants and are out of work due to the squeeze on the national budget. On average, contract teacher receive monthly salaries of 2,000 Kenyan shillings, a fraction of the 8,000 Kenyan shillings price tag of official teachers. The MoE must further provide benefits, amounting to as much as 4,000 Kenyan shillings, to its civil servants.

In January 2005, International Child Support Africa (ICS) initiated a two year program that examines the effect of contract teachers on education in Kenya. Under the program, ICS will give funds to local school committees to hire one extra teacher locally. An initial 2004 pilot conducted on 10 randomly selected schools (out of a 20 school sample) has show great potential, and the full program will be carried out in randomly selected primary schools in the Butere/Mumias and Bungoma Districts in Western Kenya.

Researchers will examine three key components of educational attainment through this project: class size, teacher's incentives, and peer effects. Smaller class sizes may improve a teacher's ability to experiment with different teaching methods and will allow the teacher to provide more individualized attention to students. The impact of the smaller class size will be examined through data on promotion rates, drop out rates, test scores, and attendance. The research will also examine how the local hiring of teachers affects teacher's attendance and performance and how this component affects student outcomes. The local hiring of teachers may provide a cost-effective alternative to the civil servant model if locally hired teachers are indeed as effective as civil servants. Finally, through the randomized design, researchers will also evaluate the effect of peer effects. With an extra teacher, the need to divide students into two classes provides an opportunity to examine how different peers will affect a given student's performance.

Tests were administered to all students in the study schools in the grades of interest both at the beginning, middle and end of the school term. This allowed the impact evaluation to focus on improvements rather than the level of performance. (See Discussion Topic I)

Randomization of the Balsakhi Program

In 2000, Pratham was planning to expand the balsakhi program, which offered an opportunity for evaluation. They had already been working in schools in Vadodara, a large city in Gujarat, and now planned to move into the remaining 98 municipal schools. Pratham also had expansion plans for Mumbai. Resource constraints precluded the possibility of assigning multiple balsakhis to each school; this limitation, along with the desire to conduct a program evaluation, suggested a randomized experiment.

Researchers were interested in determining what, if any, effect a balsakhi has on students by comparing the change in test scores between schools that received balsakhis (treatment group) and schools that did not receive balsakhis (comparison group). Specifically, researchers had determined to test the balsakhi's possible effect on students in standards three and four in Vadodara and students in standards two and three in Mumbai. In order to stay within the budget, it had been determined that the evaluation would run for two years. Within this period, researchers hoped to examine the effect of the balsakhi on different grades, in different subjects, and over varying spans of instruction.

The research team faced some design problems. First, the nature of the evaluation calls for some schools not to receive balsakhis, but schools would want to participate in the evaluation only if they were to gain something. The exclusionary nature of randomization was therefore politically troubling, but without a comparison group, it would be difficult to attribute any improvement in attendance or achievement to the balsakhi program.

Second, the assignment of schools to groups must be random, so that, on average, the two groups are indistinguishable from each other and represent the general population. Non-randomized group assignment can lead to misleading results. Schools with the lowest initial pre-test scores may have the greatest potential to improve, or conversely, the weaker students in these already low-performing schools may overwhelm the balsakhi's ability even if she were able to help weak students in an average school. In an evaluation design where balsakhis are selectively assigned to the initially weaker performing schools, any results from the data analysis may be due to *either* the balsakhi *or* the initial non-randomized assignment of balsakhis. Randomization aims to eliminate this concern since with randomized groups, the evaluation results provide clear evidence that results are due to the balsakhi, and not to any intrinsic difference in treatment and comparison schools.

Discussion Topic 1: Why is a randomized control group necessary?

Some people might consider that a random treatment/comparison design is costly or politically difficult to maintain and to evaluate and that one can compare students who received the program to another set of students who did not receive it. However, randomization is crucial to an unbiased evaluation. The importance of randomization becomes apparent by comparing other plausible, but ultimately misleading, comparisons that researchers could make without the benefit of a randomized control group.

Fallacy 1: Within a grade and school assigned a balsakhi, compare the post-test scores of students who received tutoring to the post-test scores of those who did not.

Figure 2a shows test scores of children that received the balsakhi and of those that did not receive the balsakhi. It suggests that the balsakhi has a negative effect on students' test scores. This conclusion is invalid though. Students sent to a balsakhi are most likely to know less material before any tutoring. This is exactly why they require remedial help. Thus even if the balsakhi helps her tutored students to improve their test scores, this improvement will likely go undetected in this simple differences comparison in a non-randomized framework. This type of analysis does not account for the variation in initial achievement levels of students.

Fig 2a

Fig 2b

Fallacy 2: Within a grade and school assigned a balsakhi, compare the change in test scores of students who received tutoring to the change of those who did not.

Figure 2b shows that the balsakhi has a large positive effect in improving students' test scores. This conclusion is also misleading. Even though this comparison attempts to detect differences in improvement (as opposed to differences in the post test scores), the result is likely to be biased. Since tutored students generally have such low initial test scores, their improvement is potentially dramatic compared to high performing students. For an extreme example, a student with an initial score of 0% has a much higher margin of improvement than a student with an initial score of 100%. However, the initially low-performing student would almost certainly have a larger improvement than the high-performing student *with or without a balsakhi*.

Ultimately the following randomization design was judged to be optimal: Researchers first determined at which levels to stratify the sample. Stratification means schools are pre-sorted into groups based on observable characteristics, such as language of instruction. Then from each of these groups, schools are randomly selected to be in the experimental and comparison groups. In the case of language instruction, this assures

that there will be an equal number of Gujarati, Hindi, and Marathi language schools in the experimental and comparison groups.

Schools were first stratified by language of instruction and then by student-teacher ratios. For Hindu language schools, there was further need to stratify according to gender of school. Furthermore, in the Mumbai implementation, schools were stratified by their pre-test score performance as well. From these stratified groups, schools were randomly classified as Group A or Group B.

Discussion Topic II: Stratification

Stratification attempts to make sure that the randomly assigned groups are balanced in terms of observable characteristics, such as language of instruction, student-teacher ratios, and gender. However, the concept of randomization entails blindly dividing up a sample into two groups. Why is it that stratification of the sample is necessary prior to randomization?

The Mumbai program had an additional level of stratification, pre test score performance. Presumably, researchers feared that even with randomization, the two groups could have appreciable differences in their pre test scores. Given that this is a concern, why was such stratification not used in the Vadodara sample? Consider some of the pros and cons with stratification and when stratification is not necessary.

The exercise that accompanies this case should help you think through some of these issues.

Confirming Randomization

After stratification and randomization, the research team still had to confirm that Group A and Group B were well balanced, specifically that schools in one of the groups did not have a disproportionate number of schools with certain characteristics. This was done easily by using summary statistics of the two groups to make sure that the random assignment did not produce one group that had higher pre test scores, on average, or differences in any other school level variables that might bias the effect of the balsakhi.

If differences are found in the two groups, then there are some possible solutions. If the imbalance is discovered prior to the program implementation, it is possible to re-run the randomization until the two groups are indeed adequately similar in their original characteristics. If the problem is discovered after program implementation, then there are some statistical tools you can use to correct the error.

Problems with randomization result from the practical limitations of stratification. When there are many dimensions on which the population varies, the researcher has to choose how he wants the sample stratified, since it will not be possible to stratify along every dimension. The schools in the sample had additional observable characteristics, such as whether they held morning or afternoon sessions, their geographic location, and their Muslim student population. The researchers chose not to stratify along those dimensions,

and thereby ran the risk that the two groups, A and B, would be very different along a particular dimension. There is no perfect answer to the question of how one stratifies to avoid this possibility. A rule of thumb is to stratify by the variables that are most likely to have some biasing effect on the program; subsequently, it is important to confirm that there are not big differences in treatment and control groups across other possible confounding variables.

Randomization Design

The design was a modified lottery which randomly assigned group assignment at the class level. Each school had two grades participating in the study, but the assignment of grade 3 in a particular school immediately fixed the assignment of grade 4 in that same school.

Discussion Topic III: Level of Randomization

With the balsakhi program, researchers could have randomized at a different level. Was randomizing at the class level the right choice? Consider the following designs.

Randomization at the School Level

To save on possible administrative costs, researchers might have decided to simply randomly assigned schools to have balsakhis. In this design, schools in Group A would receive balsakhis for both grades in the first year and no balsakhis the second year. Similarly, schools in Group B would receive no balsakhis in year 1 and balsakhis for both grades in year 2. This would allow researchers to monitor the balsakhis more easily since they would have to scrutinize only half of the schools each year. Would there be drawbacks to this approach? What might they be?

Randomization at the Individual Level

Alternatively, researchers could have randomized on the individual level. Due to the variation in school quality, the highest achieving students at say school X may still have lower levels of achievement than lower achieving students at school Y. Some people might argue that it is more equitable to target balsakhis to the lowest achieving students in the entire sample. This suggests a possible approach to randomization.

Suppose the following scenario. With a pre-test, researchers use a cutoff score to identify the lower-achieving students in all schools “eligible” to receive balsakhi tutoring. This is the relevant sample of students from which half the students (in each grade level) are chosen to receive balsakhi tutoring. Due to proximity of primary schools in an urban Indian environment, students may sometimes go to a neighboring school for tutoring. Thus, if all the students of one grade of one school are low achieving, then it is possible that all of them have an equal chance of being assigned to the balsakhi. Conversely, if a school has only one or two low-achieving students, only they also have a chance of balsakhi assignment, but would likely travel to another school for this. How does this design affect the treatment and comparison groups in terms of a class size effect? ...in terms of a balsakhi effect on low achieving students?

In Vadodara for the 2001-02 school year, Group A schools received balsakhis for grade 4; Group B, for grade 3. In 2002-03, Group A received schools for grade 3; Group B, for

grade 4. Additionally, in this second year, 25 extra schools entered the study, and these were randomly assigned to one of the groups. The randomization design is shown in the table below:

Table 1: Balsakhi assignment by grade and randomized group

	Year 1 (2001-02)		Year 2 (2002-03)	
	3 rd grade	4 th grade	3 rd grade	4 th grade
Vadodara				
Group A	NO	YES	YES	NO
Group B	YES	NO	NO	YES
Mumbai				
Group A	NO	YES	NO	YES
Group B	YES	NO	YES	NO

Pratham also set up a randomized evaluation of the Balsakhi program in Mumbai in 2001-02 to one of the city's wards (where Pratham had had some presence before). The L-ward included 62 schools, and the randomization was similar to the one employed in Vadodara. Thus the program was evaluated in two different cities in two different States, which ensures that the program is not so specific that it only works in one particular city environment.

To better understand the thought process that drives a successful randomization design, consider possible designs for the extra teacher program in Kenya. The box on the next page will aid you in this exercise.

Discussion Topic IV: Alternative Randomization Designs

The randomization design is a unique design, and researchers could have gone with more standard models. Consider how the implementation of one of the following designs would have affected the program either through political feasibility, costs, or analysis.

Lottery: Under a pure lottery model, each grade in each school would be its own "observation". Through random assignment, it is therefore possible that some schools would receive two balsakhis one year (one each for grades 3 and 4) and some schools would receive no balsakhi one year. However, any grade cohort (within a school) that receives a balsakhi the first year would not receive one the second year. Each school would still receive exactly two balsakhis over the two years though.

Phase In: Under a phase in model, each grade in each school would eventually receive a balsakhi. Rather than varying who gets to participate in the program, the researchers randomly vary the timing of participation in the program. Every grade cohort in every school in the sample will benefit from a balsakhi at some point in the program duration. For example, say originally the study was to include 300 balsakhis employed over the 2 years, implying that there would be 150 schools (300 classes) in the study. Under a phase in model, there would be 100 schools (200 classes). In year 1, 100 classes would randomly receive a balsakhi and in year 2, all 200 classes receive a balsakhi. In addition to the reduction in the school sample size, how else does the phase in model affect the possible comparisons?

A Comparison to Kenya

Part II: Randomization Design of the Extra Teacher Program

The Extra Teacher Program in Kenya addresses questions similar to those investigated by the balsakhi program. The researchers have arranged a randomized design that explores three separate issues of educational attainment:

1. The effect of smaller class sizes
2. The effect of hiring teachers locally
3. The effect of having students of the same (or different) quality in a class

The sample size for control and treatment schools is 330. ICS Africa, the implementing NGO, already operates several other randomly designed education and health evaluation programs in the region. These include AIDS education programs and de-worming pill treatment programs. Most schools in the region have already or are currently receiving the benefits of one or more of these programs through ICS. Because of the widespread involvement in other areas, it is plausible for researchers to have some pure comparison schools in this study if necessary.

The structure of the program is important when considering the evaluation design. The extra teachers will be locally hired and generally equally qualified to the government-hired teachers. Thus, the main effect of having a local teacher will be the teacher's accountability to the local village school committee, which will have the ability to extend or terminate the contract. Anecdotal evidence from the pilot indicates that, if anything, parents prefer the local teachers to the government teachers.

Currently, the largest classes, by far, are all in school's first grade. Among pilot schools, the average class size was 94.6 pupils. In schools that receive an extra teacher, the first grade class will be divided into two separate classes; the local and government teacher will each teach one of these newly formed classes.

How should the schools be randomized? Note, that given the very large sample size it is possible to run several different treatment groups designed to look at different questions. Different randomization strategies may be used to answer different questions. Consider some of the following key points:

- At what level should the initial randomization occur?
- Is it necessary to use a phase-in model or an original randomization design as in the balsakhi or will a simple lottery suffice?
- Is it necessary to stratify? If so, by what characteristics?
- In addition to simply *providing* smaller classes, are there different ways to divide students into these classes among schools that will be treated?
- What problems may arise if local teachers (or government teachers) are always teaching a certain class type? Is there a fairness issues in assigning teachers?
- If students are divided strictly by ability, might there be parental opposition? How else could you divide students
- When should teachers be asked to divide the class by ability? Which teachers in the sample should be asked to do this exercise?

Keeping in mind the three main issues that researchers will examine with this program, create a chart which shows your randomization design. Based on your design, what groups will you compare to answer the question of classroom effects? ...of the effectiveness of locally hired teachers? ...of peer effects?

How does the program structure of ETP compare to that of the balsakhi program? Why are researchers able to answer more questions with ETP? How does the randomization design depend on the program structure?

Summary of Results:

Before examining test scores in the balsakhi program, researchers had to be certain that the composition of the randomly assigned classes had not changed due to the program. For example, perhaps classrooms assigned balsakhis would have, on average, lower test scores because low-performing students in schools without balsakhis simply drop out at higher rates. In this scenario, the non-balsakhi schools would appear to perform better when the “performance” is in fact due to differential attrition rates between the two groups. However, careful analysis of attendance data shows that there were no measurable effects on attendance or drop out rates from being a treatment school.

The researchers then examined the change in test scores (post minus pre) for treatment and comparison groups. The data below is representative average test scores for fourth graders in Vadodara for the 2002-2003 school year.

Table 2: Analysis of Grade 4 students in Vadodara (2002-2003 school year)

	Treatment	Control	Difference
Panel A: Pre test scores of grade 4 students in Vadodara			
Sample size (number of students)	3167	3170	-3
Average Math score (%)	31.1	29.7	1.4
Average Verbal score (%)	34.8	33.2	1.7
Average Total score (%)	33.0	31.4	1.6
Panel B: Post test scores of grade 4 students in Vadodara			
Sample size (number of students)	3003	3007	-4
Average Math score (%)	57.5	49.8	7.6
Average Verbal score (%)	51.7	45.7	6.0
Average Total score (%)	54.6	47.8	6.8
Panel C: Change in Scores from Pre test to Post test			
Change in Math score (%)	26.4	20.1	6.2
Change in Verbal score (%)	16.9	12.5	4.3
Change in Total score (%)	21.6	16.4	5.2

The average balsakhi school student had a score improvement from the pre test to the post test of 26.4% on the math portion of the exam while the average comparison school student had a score improvement of 20.1%. The difference in difference, 6.2%, is indeed statistically significant (*see text of the academic paper for the formal model*). These results generally held true for both math and verbal, for both grades, and for both cities. The two year effect of the balsakhi is even more substantial than the one year effect.

Even with these encouraging results for the average student in the class, researchers still wanted to examine whether the increase was the result of one (or a combination) of two factors. The average test score for the entire class of a treatment group could increase because the balsakhi did indeed provide the remedial help, thereby increasing test scores

of the lower achieving students of the class. Alternatively, the improvement in the pupil teacher ratio, achieved by the removal of the lower achieving students in the class, could provide more effective teaching from the official teacher to the higher achieving students of the class.

A problem in the program design prevented researchers from examining this question without additional statistical manipulation of the data. Though it was known which students in a balsakhi class actually received help from the balsakhi, the researchers had no way of knowing who were the students in the control schools who would have gone to the balsakhi had it been a treatment school. To solve this problem the researchers had to make use of a statistical model and some additional assumptions. The resulting statistical analysis did provide strong evidence that the balsakhi-tutored students (the weaker performing students) benefited the most from having a balsakhi assigned to their class. The analysis also showed that there were no indirect effects on the remaining non-balsakhi-tutored students from the balsakhi reducing the effective class size.

Moving Forward

Using a randomized evaluation of the balsakhi program, researchers found strong evidence of the immediate effects of remedial education in teaching basic competencies to under-achieving students in Vadodara and Mumbai schools. Through the carefully planned randomization design, researchers were able to determine that the program successfully targeted improving the weakest students in the overfilled classrooms. Additionally, researchers found no benefits resulting from either the reduced class sizes or more uniform student achievement levels that resulted from the removal of weaker students to their balsakhi tutorials for part of the day.

The balsakhi program is one cost-effective method of helping students who have fallen behind in their education to catch up to the rest of their class. The extra teacher program in Kenya provides another opportunity to examine key issues in educational attainment, such as classroom size, peer effects, and teacher accountability. The more complex randomization design in the Kenyan program will allow researchers to examine multiple questions with one program.

With the global effort towards universal primary education, considerable strain has been added to developing countries' available resources. Children at the bottom end of the distribution, who have the most to learn, often lose out most in school systems plagued by large classrooms, mixed student populations, teacher shortages, and a lack of basic infrastructure and supplies. As local communities and NGOs continue to explore new solutions to these dilemmas, randomization is a powerful tool to measure program effectiveness in providing education in the developing world.

Case 3: Women and Political Representation in India

Measuring the Effects of Reservations

This case study, with kind permission of the authors, is based on “Women as Policy Makers: Evidence from an India Wide Randomized Policy Experiment”; Raghavendra Chattopadhyay and Esther Duflo, *Econometrica*, 2004 as well as “Unappreciated Services: Performance and Perceptions”; Esther Duflo and Petia Topalova, Mimeo, MIT, 2004.

Throughout the world, women are underrepresented in government. In 2004, only 15.6 % of the parliaments of the world were composed of women. The low presence of women in government means that they are disempowered and have less influence over the decision making process.

To address this issue, political reservations for women have been implemented by many governments. It is not clear, however, what effect reservations have on the political process. Will candidates that come to power through reservations be less skilled? Will they be acting as proxies for other more powerful members of society? In systems where reservations exist for women, do policies, in fact, better represent the preferences of women? Do women and men really have different policy preferences? Legislation passed in India in 1992 provides a test case for addressing these questions.

Panchayats and Rural Self-Government

India is poor because the villages of India are poor. India will be rich if the villages of India are rich. Panchayats should be given greater power; for we want the villagers to have a greater measure of real swaraj [self-government] in their own villages. – Jawaharlal Nehru, first Prime Minister of India

Independence must begin at the bottom ... it follows, therefore, that every village has to be self-sustained and capable of managing its affairs. – Mahatma Gandhi

Panchayats are an old form of village government in India. When India became independent in 1947, Indian leaders wanted to empower them and incorporate them into the new country's system of governance. In fact an article was written in the constitution to give Panchayats the powers necessary to "function as units of self-government". However, in practice, political and financial support from the central government for the Panchayats disappeared in the 1950's and 1960's in most states. It was only in Karnataka, West Bengal, and Kerala, that Panchayats continued to be taken seriously.

The idea of Panchayat government was revived in the late 1980's when Rajiv Gandhi, then Prime Minister, began canvassing for rural support. A proposal to re-invigorate the Panchayats was widely popular, but it was defeated. Opposition political parties were strongly represented in the states and reluctant to give power to local village councils. In 1992, though, the bill was rewritten and passed. It became the 73rd Amendment to the Indian Constitution under Prime Minister Narasimha Rao. The rural development minister at the time observed "[this] casts a duty on the centre as well as the states to establish and nourish the village Panchayats so as to make them effective, self-governing institutions".

Seventy percent of India's population live in rural areas and are subject to the changes brought about by the 73rd amendment. The amendment sets guidelines for the states, which have the final authority to determine exactly what powers are delegated to the Panchayats. The 73rd amendment requires that the states supervise, every five years, direct elections for council members at the district, block and village levels.¹

¹¹ In India, the district is the principal subdivision within states. There were 476 districts with an average population of 1.8 million in the early 1990s. The council at the district level is known as the Zilla Parishad. A block is a large subunit of a district. The block level council is known as the Panchayat Samiti.

The lowest level of the Panchayat is the Gram Panchayat (GP). The size of a GP varies from state to state but each GP covers between 1 and 12 villages, and between 2,000 and 10,000 people. Each ward, which may be a village, or a fraction of a village, elects a council member. A Pradhan (Panchayat Leader) is then elected, either directly or indirectly, by the council members. The councils must hold meetings, or Gram Sabhas, several times a year with a quorum of villagers in attendance. At one of these meetings, villagers must approve next year's budget and this year's activities.

The GPs are responsible for enacting schemes for economic development and social justice determined by the states in accordance with the 11th schedule of the act. The 29 areas of responsibility from the act are listed in the appendix.

The Panchayat is primarily responsible for implementing development programs, as well as identifying the needs of the villages under its jurisdiction. The major responsibilities of the GP are to administer local infrastructure such as public buildings, water and roads. The GP also identifies recipients for welfare programs such as widow's pensions, old age pensions and maternity pensions. The main source of financing is still the state, but most of the money which was previously earmarked for specific uses is now allocated through four broad programs.

- (1) The Jawhar Rozgar Yojana (JRY) - infrastructure such as irrigation, drinking water, roads, repairs of community buildings, etc.
- (2) A small additional drinking water scheme.
- (3) Funds for welfare programs (widow's, old age and maternity pensions, etc.)
- (4) A grant for GP functioning.

In many ways, the most striking part of the 73rd amendment is the institution of reservations for women. The framers of the amendment thought that the hierarchical nature of Indian village society would prevent all groups from having an equal voice (or a voice at all) in local governments. Women and scheduled castes and tribes would continue to be marginalized from the decision making process. In order to prevent this from happening, the amendment created a system of reserved seats for women and "backward" castes in the Panchayat council and council leadership positions.

The Debate Over Reservations

The idea of political reservations is a controversial one. First, there is the question of constitutional legitimacy. Since quotas restrict the election choices of voters, some consider them to be undemocratic. There is also the possibility that quotas reduce the quality of candidates running and result in less effective government. There is even a question about the premise on which quotas are based, that the identity of the elected representative matters for policy outcomes. It may be that, once elected, a candidate will support policies which reflect the preferences of the electorate or party rather than her preferences as a woman or member of a scheduled caste.

Those who favor quotas, however, feel they may make democratic institutions stronger. Some see unequal representation as the result of prejudices which themselves undermine the institutions of democracy. Exposing women and backward castes to decision making processes and representing them in positions of power is a way to lessen the prejudices that prevented these groups from being elected in the pre-quota system. Quotas may be necessary to make decentralization work for poor people. In a centralized administration, groups that are nationally disadvantaged can be organized in relatively powerful lobbying groups, and demand some specific redistributive measures. Many parties in Indian states represent the interest of the lower castes, for example. But at the village level, members of disadvantaged groups may be unable to fight for their rights. Decentralization may then lead to a worsening of their situation.

But this argument suggests that this situation would be affected by the identity of the Panchayat leader. It is not obvious that it should be the case. If the electoral and the participatory system is vibrant, those elected should reflect the policy preferences of the electorate, whatever their own identity. On the other hand, if it is weak, the nominal leader may be dominated by the local elite. This may be even more likely to happen if he or she happens to belong to a historically disadvantaged group.

The model in which candidates commit to policies reflecting the preferences of the electorate may not apply in practice. Strict campaign promises that are enforced are rarely if ever seen. Enforcement of campaign promises may occur through the mechanism of voting out incumbents or, in the Indian case, through the refusal to approve his budget at the community meetings. However, such enforcement is certainly not complete. In this case, one may expect that the identity of the policy maker will affect outcome.

Reservations for Women

"The transfer of power to one million women elected local representatives — many of whom are malnourished and illiterate — is the greatest social experiment of our time."

Joan Holmes, President, The Hunger Project

"You can tell the condition of a nation by looking at the status of its women."

Jawaharlal Nehru, first Prime Minister of India

The condition of women in India, relative to men, is by many measures very poor. According to the last census the ratio of women to men has declined to 93/100. Women work longer hours than men and have less access to education and health care. The maternal mortality rates in rural India are among the highest in the world. Similarly, malnutrition rates are high, and higher for women than men. According to an article published by UNICEF in the 1996 Progress of Nations "gender [in South Asia] has been the most statistically significant determinant of malnutrition among young children and a

frequent direct or underlying cause of death among girls below age 5". Women also earn less than men, and as in many other countries, their representation in government has been traditionally very low.

There is plenty of evidence from India and elsewhere that women have greater preferences for child health and nutrition than men. For example, the share of food in the budget tends to increase when the share of women in the family income increases. If this is the case, increasing women's participation in government is beneficial not only for reducing gender inequity but also to generate more favorable outcomes for children. Moreover, women's traditional responsibility to fetch water means that having women in parliament – thereby enhancing the decision making power of women – may lead to better water and sanitation infrastructure, a leading factor in reducing childhood mortality. As the president of the World Bank, James Wolfensohn, clearly puts it, empowering women is viewed by many as a "win-win" proposition:

"Education for girls has a catalytic effect on every dimension of development: lower child and maternal mortality rate; increased educational attainment by daughters and sons; higher productivity; and improved environmental management. Together, these can mean faster economic growth and equally important, wider distribution of the fruits of growth ... More education for girls will also enable more and more women to attain leadership positions at all level of society: from health clinics in the villages to parliaments in the capitals. This, in turn, will change the way societies will deal with problems and raise the quality of global decision making."

In addition, many believe that women would bring to government a cleaner style than men. Numerous experimental and survey-based studies find that women are more likely to exhibit "helping behavior" (Eagly and Crowley, 1986), take stronger stances on ethical behavior (Glover et al., 1997, Reiss and Mitra, 1998) and behave more generously when faced with economic decisions (Eckel and Grossman, 1998). The British Council conducted a study in 8 countries in East and Central Africa in late 2001, interviewing 800 people on their perception of women political leaders. The study found that more than 70 percent of people thought women politicians performed better than or equal to men, more than half of those interviewed felt that women politicians were less corrupt than men and cared more about basic community needs than men. Recent attention has also been drawn to the potential of advancing women as a means of fighting corruption. Swamy et. al. (2001) find that in the 43 countries surveyed in a "world values survey," women are less likely to say illegal or dishonest behavior is justifiable. Swamy also finds that greater labor force participation and greater government involvement by women is related to less corruption.

These beliefs have translated into action in at least two other cases. In Mexico City, the police chief rescinded the ticket-writing authority of the city's 900 male traffic policemen and created a new force consisting exclusively of women, in an attempt to reduce corruption. A similar policy has been administered in Lima, Peru, where it is claimed there has been a fall in corruption after the introduction of women.

It was with these ideas in mind that the 73rd amendment has reserved seats in the Panchayats for women and scheduled castes and tribes. Specifically, the amendment

stipulates that one third of all council member seats are reserved for women. In addition, one third of all council leaders or Pradhan positions are reserved for women. Today, as a result of this amendment, there are about one million women elected to the village councils, or Gram Panchayats, in India.

The reservation of seats to women was determined on a random basis. In practice in most states, Panchayats reserved for women were selected randomly (every third GP in the order of their serial number), within each list of reservation status (reserved for Scheduled Castes, reserved for Scheduled Tribes, Non-reserved for SC or ST). Given this random allocation of seats all that is left for the researcher is to determine what data to collect, and how much of it.

While reservations have been part of the political landscape in India for a long time for scheduled castes and scheduled tribes since independence (there are reservations for political seats, government jobs, places in college, etc...), it is the first time that reservations were enacted for women. This experience was therefore closely watched, by proponents of reservations and their adversaries alike. Were women going to be effective leaders? Were they going to be less corrupt than men? Were other women going to be empowered by the presence of women politicians? Would the types of investments made by the Panchayat be different? Or would the new leaders simply act as proxies for their male relatives or other powerful people in the village, leading to less accountability and worst governance?

Field Observations

Some observers have questioned the possibility that women as leaders could have any effect, pointing out that many of those elected through the reservation system were illiterate and ignorant of the political process. It has also been argued that when the seats of male pradhans became reserved, they would simply nominate their wives who would continue to carry out their husband's policies. Finally, many of the newly-elected women faced strong prejudices due to their gender. In several particularly conservative states, acts of violence have been directed at women who undertook GP president responsibilities (Mathew and Nayak, 1996).

Yet, despite the opposition, some argue that:

“Elected women have proved to be more responsive, sympathetic and caring than their male colleagues. They are found to have greater integrity, more concern about issues like drinking water, health care and children’s education in comparison to their male counterparts.” (Mathew, 2001).

An evaluation by the NGO “Sahayi” of the performance of 6,200 women representatives in the various Panchayats in Kerala found that women elected in the second round of reservations were more educated, self-confident, and self-reliant than the previous batch.

Field researchers have suggested that the entry of women into the PRI (Panchayat Raj Institutions) have had some effect on local government, and described reasons that may limit women leaders' effectiveness:

“In Madhya Pradesh women in the PRIs have made an impact in sectors like primary education, health, drinking water, watershed management, formation of self help groups, excise related issues like location of liquor shop etc. However, they have yet to make an impact in areas like agriculture, land improvement, minor irrigation, animal husbandry and rural industries, but this is more on account of the fact that the extension machinery is largely unable to address women or their needs”

Another field researcher noticed increased attention on women and girls' literacy, as well as reproductive health:

“One major outcome of women's entry into PRIs is a tremendous demand generation for female literacy and girl child education. The coming of women in the PRIs has helped focus attention on [issues of women's reproductive health] more sharply. In some Gram Panchayats with the help of NGO intervention, the women sarpanches have concentrated on the need for better health infrastructure in the rural areas”

Many also believe that the effect of the reservation policy will be different in different states. While it may be effective in states with a strong tradition of local democracy or in states where women are in a better position, many fear that, in the northern states where women are severely discriminated against, the policy is likely to be perverted and ineffective. To this, proponents argue that it is precisely in those states that the entry of women in politics may make the bigger difference.

The Project

Your evaluation team has been entrusted to determine the effects of reservations for women in the Panchayats. You want to go beyond the anecdotes, but at the same time, you do not want to limit your analysis to a simple count of what types of public goods are available in different Panchayats (although this definitely needs to be part of it). You would like the project to address all the dimensions in which reservations for women are changing the shape of local governance in India.

Discussion Topic 1: What outcomes are likely to be affected by the reservation policy?

Before embarking on an evaluation exercise, you need to have a clear idea of what the likely impact of the program will be. It is on those dimensions that you think will be affected that you will try to collect data.

Given the background information, what are the main areas on which the reservation policy should be evaluated? In what different areas might we expect to see a difference as a result of reservations?

Box 1: Evaluation Area, Birbhum, West Bengal and Udaipur, Rajasthan

There are two districts of India where you can collect data, Birbhum in West Bengal and Udaipur in Rajasthan.

The district of Birbhum is located roughly 125 miles from the state capital, Calcutta. It is composed of two distinct regions. In the west is the mostly barren fringe of the Chota Nagpur plateau. In the east is the fertile, and densely populated, Gangetic plain. Birbhum had a population of 2.56 million in 1991 which increased to 3.01 million in 2001. Agriculture was the main economic activity; and rice, the main crop cultivated. The 1991 male and female literacy rates were 50% and 37%, respectively. In 2001 the female literacy rate rose to 60%. The district is known to have a relatively well functioning Panchayat system.

Unlike most states in India, West Bengal devolved powers to its Panchayats in 1978. Since then it has had a functioning Panchayat system with five year elections. Following the passage of the 1992 amendment, West Bengal gave additional responsibilities to its Gram Panchayats. Specifically, they were able to establish and administer informal education centers (SSK). The last Panchayat election took place in 2003. This was the second election where the reservation system was in place.

Udaipur district in Rajasthan is a predominantly “tribal” district, with a high poverty rate and a very low female literacy rate. The district has a population of 2.63 million according to the 2001 census. The population density of 196 persons per square kilometer is higher than the state average of 165 persons per square kilometer. However, more than 46% of the tribal population lives in remote villages accessible only by foot. Wheat and maize are the main cultivated crops and the district is rich in minerals like copper ore and limestone.

Early marriage of girls is prevalent in the district with nearly 70% marrying before turning 18. The sex ratio is 972/1000 reflecting the poor condition of women in Rajasthan in general. There are some indications that things are improving, however: between 1991 and 2001, the female literacy rate doubled from 20% to 44%.

In Rajasthan, the first Gram Panchayat elections were held in 1995 followed by a second election in 2000. Gram Panchayats in Rajasthan have the authority to spend money on local infrastructure but not to run their own schools.

There are several methods available to you and your team to answer questions about the effects of reservations for women in the Panchayats. Here are some examples of what could be done, with some ideas of the resources each of these activities would require, in term of man days (we will assume here that all other expenses can be computed using a simple overhead rule).

Pradhan Interview

Your team can interview the Pradhan. You can use this interview to collect information on a wide variety of subjects, from the Pradhan's background, education and political goals to the political involvement of her/his family members to the specific investments in public goods she has undertaken during her time in office. You can also ask to see the Pradhan's balance sheets, which are supposed to be public information.

A strength of interviewing the Pradhan and asking directly what investments he/she made in the GP is that you have a record for investments in all GP villages. You are not constrained to work with data from a subsample. Unfortunately, there is a serious issue of concern with this approach. The Pradhan's recollection of past policy initiatives may be imprecise and/or the Pradhan may lie. The cost of doing a pradhan interview is 1 man day/interview.

Participatory Resource Appraisal (PRA)

This is a method of gathering data at the village level. The PRA is a map of the village drawn with the help of 10 to 20 villagers. The map delineates schools, roads, wells, scheduled castes and tribe (SC and ST) areas, cultivated land and energy projects among other things. The villagers are asked to identify all available infrastructure in the village. It is also possible to ask, for each public good, when it was built or repaired. This is an extremely accurate method of gathering information on the public goods available in the village. An example of such a map is presented on the following page.

Moreover, the PRA is also an occasion to ask villagers general questions about the quality of different public goods in the village, about the participation of women and men in various activities (such as village meetings), and whether men or women from this village have complained about various issues to the Pradhan. At the PRA, you can obtain minutes of the past Gram Sabhas (this is much less detailed than the transcript), recording both attendance and the main issues raised. The drawback of such focus groups is that they do not represent the opinion of a representative sample of villagers.

Three man days are sufficient to complete a very detailed PRA and to complement it with focus groups. In addition, it will take one man-day to travel from one GP to the next, and half a man day to travel from one village to another within the same GP.

Participatory Resource Appraisal (PRA), Damdama Panchayat

Transcript of Gram Sabha

You could obtain more detailed information about what happened during the Gram Sabha by sending investigators to attend the meeting, and record what happened. They could both maintain an observation sheet (Who speaks? When? For how long?), as well as record the entire proceedings on a tape, which could be transcribed, translated, and that you can directly analyze. With this process, you will have a chance to observe in

detail the functioning of local democracy. An extract of such a recording (conducted in Karnataka) is shown in the appendix to this case. Attending the meeting and transcribing and translating takes a long time: you need to budget at least 5 man days for each Gram Sabha you decide to cover in this way.

Household Interviews

You also have the possibility to send a team of investigators to interview a sample of households in each village. Interviewing individuals would allow you to collect both objective information and perceptions from all households members.

Along with the PRA the household surveys allow very detailed data to be collected. However, this is the most expensive source of data. A short questionnaire (a simple questionnaire without physical measurement, and focusing on interviewing only one or two household members) will cost the research group roughly $\frac{1}{2}$ man day per household, a long questionnaire (involving health measurement for example) will cost up to a full man day per household. Moreover, you need to start with a PRA to establish the household list from which your household can be sampled.

Box 2: Sample Size, Power and Clustering

When we select a sample of GP's for our study, we hope that the sample is representative of the general population. Otherwise, relationships that we find in our data may not hold in the 'true' population. If we randomly select GP's from the total GP population, then our sampling error will decrease as our sample size increases. So we may choose a sample size as large as our budget allows. Or we can work backwards and determine the sample size needed to gain a specific level of precision.

What affects the precision of our estimates besides the size of the sample? There is the variance of the characteristic we are trying to measure (for example, variance in investment in water) and the size of the treatment effect (how much does investment in water change with the treatment, i.e. with reservations for women). The more variance in the population, the larger the sample required to gain a given level of precision. Similarly, the smaller the treatment effect we are trying to detect, the larger the sample needed in order to detect it.

Power is a useful measure of how informative our sample is likely to be. It is defined as the probability with which we will notice a treatment effect when there is, in fact, a treatment effect in the sample.

Power varies with the method of randomization. If we randomize over GP's but are interested in measuring outcomes on individuals, households or villages within the GP, then the power of our sample decreases. This is because we expect there to be correlation between individuals, households or villages within a GP. When we use these 'sub-units' for analysis, we no longer have a truly random sample. We refer to randomization done on an aggregate of the unit of analysis as **clustered** randomization.

Choosing instrument and samples to answer policy-relevant questions

Your evaluation team may choose any number of villages or Panchayats from the districts of Birbhum and Udaipur and any combination of types of data collection listed above, provided the sampling method and the resource type do not exceed your budget.

Discussion Topic 2:

Choosing the right instrument to answer the right questions

Which of the possible data collection methods above can inform you of the impact of reservations for women on the dimensions (areas of interest) you identified in discussion topic 1? Which variables will you look at?

In determining what sampling method to use, your team will be concerned with the sample size required to get reasonable *power* for your analysis. The power is the probability that, if there is an effect of an expected size, you will be able to distinguish it from zero with a 95% confidence interval.

Discussion Topic 3: Power and Cost

Power Calculations

Start by completing the excel exercise.

How does power vary with sample size? With the effect size? With the way the sample is drawn? What is the tradeoff (in terms of budget) between choosing more villages within the same GP and choosing villages in different GPs?

Which effect on the number of investments in drinking water do you think your study needs to be able to detect to ascertain whether women Panchayat leaders did make a difference on the number of wells?

Given the magnitude of the effect you want to find, what is the smallest number of villages you need to detect the effect (from PRA)?

Does the study with the minimum number of villages necessarily have the smallest budget? Why or why not? How should you pick the villages to have the smallest budget to detect the effect? How many villages do you need?

Working within a budget

Given a budget of 900 man days, what data would you collect? Of the questions you are interested in which could you answer? Which questions that you would want to answer are you unable to answer within this budget?

Given a budget of 4000 man days, what data would you collect? What new questions could you answer?

Appendices

Appendix 1 - Responsibilities Listed in the 11th Schedule

Panchayat responsibilities. The 11 schedule of the 73rd amendment specifies 29 areas of responsibility that states may devolve to the panchayats. *Note: areas marked in **bold** are areas where independent observers have indicated that women bear primary responsibility.*

<ol style="list-style-type: none"> 1. Agriculture, including agricultural extension 2. Land improvement, implementation of land reforms, land consolidation and soil conservation 3. Minor irrigation, water management and watershed development 4. Animal husbandry, dairy and poultry 5. Fisheries 6. Social forestry and farm forestry 7. Minor forest produce 8. Small scale industries, including food processing industries 9. Khadi (homespun cloth), village and cottage industries 	<ol style="list-style-type: none"> 10. Rural housing 11. Drinking water 12. Fuel and fodder 13. Roads, culverts, bridges, ferries, waterways and other means of communication 14. Rural electrification, including distribution of electricity 15. Non-conventional energy sources 16. Poverty alleviation programmes 17. Education including primary and secondary schools 18. Technical training and vocational education 19. Adult and non-formal education 	<ol style="list-style-type: none"> 20. Libraries 21. Cultural activities 22. Markets and fairs 23. Health and sanitation, including hospitals, primary health centres and dispensaries 24. Family welfare 25. Women and child development 26. Social welfare, including welfare of the handicapped and mentally retarded 27. Welfare of the weaker sections, and in particular, of the scheduled castes and the scheduled tribes 28. Public distribution system 29. Maintenance of community assets

Appendix 2: Plan Outlay for Annual Plan 2000- 01 for Schemes/Programmes of State Governments as per Eleventh Schedule

(Rs Crore)

Name of Scheme/Programme	Outlay
Crop husbandry	1268.77
Soil and water conservation	643.50
Animal husbandry	354.19
Dairy development	49.87
Fisheries	205.95
Forestry and wildlife	1393.03
Plantations	4.63
Agricultural research and education	292.21
Agricultural finance institutions	61.63
Other agricultural programmes	98.18
IRD and allied programme	516.16
NREP/JRY	1161.22
Other programmes like EAS, etc	1062.46
Land reform	294.08
Minor irrigation	1907.93
Non conventional sources of energy	119.43
Village and small industries	800.87
Roads and bridges	8128.44
Road transport	1265.30
Inland water transport	16.74
Other transport services	614.50
General education	4972.07
Technical education	422.49
Art and culture	171.07
Medical and public health	3306.64
Water supply and sanitation	6031.74
Housing	1936.57
Welfare of SCs, STs and OBCs	1972.99
Social welfare	904.26
Nutrition	721.79
Other social services	119.86
Total	40818.65

Note: The outlay mentioned against each scheme/programme is the sum of the outlays for all the state governments allocated against each of their schemes.

Economic and Political Weekly January 10, 2004

Appendix 3: A Gram Sabha recording: Extract

Villager - Male (Speaker 1)

In our year 4 times the Panchayat and even 2 time Panchayat is also held. The sandy and market need is also described. But Panchayat needs do give all the support for the villagers for sandy and market.

[...]

G.P. Member - Male

We have put borewell but the pump is not put.

Villager - Male (Speaker 2)

Yes we will try and make it early for the borewell.
How many days you take for this.

G. P. Member - Male

We have taken good steps this but it is taking some time.

The sandy is also necessary but nobody is using this for selling or trading. So the place is not developed the shop are remaining like wise. We have done of MP quota but also we will not make that remain we will try and develop it as soon as possible

Villager - Male (Speaker 3)

Says, he is not treated properly as he is be looked low upon towards his caste.

G.P. Member - Male

But we are not saying so will you please be quite. We are not come to fight we are taking care.

Villager - Male (Speaker 4)

We have given application but what are you doing. We are very tired of giving our opinions we are very sick. We must say that government is not doing anything.

I think we must take some step against all these to government.

G. P. Member - Male

We have send the application to the HCF co-operation but we have not received any reply from the higher source so we have to wait.

Villager - Male (Speaker 4)

It is your duty to go and follow.

[....]

Villager - Male (Speaker 5)

How can you feel that happens, who is happy. There are nobody to ask you properly on the top of your voices, so you can do what ever you feel. You are taking all bribes you should give away the Panchayat you are taking 2000 Rs. Bribe you are taking 500 Rs and giving 1500 Rs to the higher ways.

How can you say that?

We have eye witness for Rs. 500 what you have taken not one we are many who have see you taking bribe.

Villager - Male (Speaker 6)

You are taking money and then saying you will do work.

G. P. Member - Male

How do you say.

Villager - Male (Speaker 7)

People who have given are here and people who have seen are here. We had given complaint to minister, but that was initially covered by taking bribe. They say that incident was not done at all. But we know that everything was done. Than he was transferred.

He is transferred.

Yes but why are you worried if he is transferred. What make you feel for that.

You should not tell all such this.

It is your faith its reality let everybody come to know. The bribe should not be entertained the transfer if such officer should be taken out first. Let the police come to the sabha when we do trouble I can face.

Case 4: Deworming in Kenya

Managing Threats to the Integrity of an Evaluation and Data Analysis

This case study, with kind permission of the authors, is based on “Worms: Identifying Impacts on Education and Health in the Presence of Treatment Externalities”; Edward Miguel and Michael Kremer, *Econometrica* Vol. 72, No. 1 (January 2004) pp. 159-217.

Introduction

Hookworm, roundworm, whipworm, and schistosomiasis infect one in four people worldwide. They are particularly prevalent among school-age children in developing countries. Intestinal worm infection rates are high throughout Kenya, especially among children of primary school age. A heavy worm load can lead to listlessness, diarrhea, abdominal pain, anemia, malnutrition, and even enlargement of the liver and spleen. In addition to the negative health and nutritional consequences, worm infections can result in impaired cognitive ability and poor academic performance. Low cost (50 cent) single dose oral therapies can kill most worms (although whipworm is sometimes harder to treat). Despite this fact, in many places, worms are not treated on a regular basis, partly because they are seen as ubiquitous and non life-threatening, and partly because reinfection is rapid and thus treatment must be regular. In the area of Kenya where the study discussed here took place, blood in stool (a symptom of worm infection) is considered a natural condition of childhood.

Scanning Electron Micrograph of Hookworm

Box 1. Disease Transmission: How Do Children Get Worms?

(Information from CDC, Division of Parasitic Diseases <http://www.cdc.gov/ncidod/dpd/parasites/listing.htm#S>)

Geohelminths

(hookworm, roundworm, whipworm)

Geohelminths are passed through contact with contaminated soil, generally by walking barefoot, or accidentally swallowing contaminated soil. Adult geohelminths live within the small intestine of their host and their eggs are passed in the feces, and often deposited into the soil.

Schistosomiasis

Schistosomiasis is caused by flukes, which have complex life cycles involving specific fresh-water snail species as intermediate hosts. Infected snails release large numbers of minute, free-swimming larvae (cercariae) that are capable of penetrating the unbroken skin of the human host. Even brief exposure to contaminated fresh water, such as wading, swimming, or bathing, can result in infection.

The Primary School Deworming Project

The Primary School Deworming Project (PSDP) was carried out by International Child Support (ICS) Africa (whose parent organization, Internationaal Christelijk Steunfonds, is a Dutch non-governmental organization), in cooperation with the Busia District Ministry of Health office. The project took place in southern Busia, a poor and densely-settled farming region in western Kenya, in an area with the highest helminth infection rates in Busia district. The program involved 75 primary schools which were phased into deworming treatment in a randomized order. The 75 project schools consisted of nearly all rural primary schools in this area, and had a total enrollment of over 30,000 pupils between the ages of 6 and 18.

In January 1998, the 75 PSDP schools were randomly divided into three groups of 25 schools each: the schools were first stratified by administrative sub-unit (zone) and by their involvement in other non-governmental assistance programs, and were then listed alphabetically and every third school was assigned to a given project group. Due to ICS's administrative and financial constraints, the health intervention was phased in over several years. Group 1 schools received free deworming treatment in both 1998 and 1999, Group 2 schools in 1999, and Group 3 schools began receiving treatment in 2001. Thus in 1998, Group 1 schools were treatment schools, while Group 2 and Group 3 schools were comparison schools, and in 1999, Group 1 and Group 2 schools were treatment schools and Group 3 schools were comparison schools (Box 2). Treatment schools were treated regularly on the basis of standard protocols (Box 3).

Box 2. Treatment vs. Comparison Schools: Treatment Timeline

1998		1999		2001
<i>Treatment</i>	<i>Comparison</i>	<i>Treatment</i>	<i>Comparison</i>	<i>Treatment</i>
Group 1	Group 2 Group 3	Group 1 Group 2	Group 3	Group 1 Group 2 Group 3

Box 3. Deworming Drugs: Who Should Receive Them?

Given the minimal side effects of deworming drugs and the expense of individual screening, the World Health Organization (WHO, 1992) has endorsed mass school-based deworming programs in areas with high worm infection.

The WHO recommends that schools with geohelminth prevalence over 50 percent be mass treated with albendazole every six months, and schools with schistosomiasis prevalence over 30 percent be mass treated with praziquantel annually.

All treatment schools in this study met the geohelminth cut-off in both 1998 and 1999 and so were mass treated with albendazole. Six of 25 treatment schools met the schistosomiasis cut-off in 1998 and 16 of 50 treatment schools met the cut-off in 1999. Following standard practice at that time (Bundy and Guyatt, 1996), the medical protocol did not call for treating girls 13 years of age and older due to concerns about the potential teratogenicity (that is, threat of causing birth defects) of the drugs (WHO, 1992). Since then, new evidence has suggested that this is not a threat, and new WHO guidelines do not exclude girls of reproductive age.

Evaluation Design: Managing Threats and Analyzing Data

In designing the evaluation, the authors faced a number of challenges related to i) the possible impact that treating children had on their school attendance, ii) the fact that not all children who were in the “treatment schools” got treated, and iii) the role children played in spreading worm infection. We will discuss each of these challenges separately.

Evaluation and Attrition Bias

When doing an evaluation of a program that targets school-age children and especially when such a program is carried out in schools, it is natural (and much more cost-effective) to collect data such as height, weight, and test scores on the school premises. Children are conveniently clustered together in one place at one time, and data collectors avoid having to travel to the house of every child. However, if being infected by worms makes children listless and sick, it may affect children's enrollment in and attendance at school. This means that there may be more children attending treatment schools than comparison schools on the day that the evaluators show up to measure everyone's height, weight, and test scores (it should also be noted that pupil absence rates in Kenya are high to start). This might have impacted their ability to measure the true impact of the program (see discussion topic 1).

Discussion Topic 1: Attrition Bias

Getting treated for worms meant that children turned up to school more often, and as a result, there were more children in treatment schools when the evaluators went to collect data at the end of the study.

Why could this potentially produce misleading results from the evaluation?

Are the children who benefited most from the deworming treatment different from the average children in the school? In other words, were the types of children who turned up in treatment schools, but who would have been absent if they had not been treated, like average children?

If these children were different from average children, in what way were they likely to be different? Were they likely to be taller, smaller, more or less well-nourished, or to have higher or lower test scores than the rest of the children in their school?

Given this, would a simple comparison of outcomes for those who were at school when the evaluators arrived overestimate or underestimate the impact of the program?

How would you decide whether attrition bias might be a problem in another evaluation? What could the evaluators do to ensure that they did not get misleading results?

Evaluation When Not Everyone Who Was Meant To Get Treated Actually Gets the Treatment?

Another complication was that not all the children in treatment schools actually received the treatment. One reason for this was that permission was required from parents and the community to treat the children. Individual permission from each child's parent was required because this was a research study. This would not have been necessary in Kenya if this had been a health program with no research component. Getting individual permission involved parents coming into the school and signing a permission slip in the headmaster's office. This is not a trivial requirement for many households: traveling to school to sign the book may be time-consuming, and some parents may be reluctant to meet the headmaster when they are behind on school fees, a common problem in these schools. Another reason why not everyone got treated was that some children were absent on the day that the deworming medicine was given.

Discussion Topic 2: When the Treatment Group Doesn't Get Treated

At first, it may appear natural that if someone who was randomly assigned to get treated doesn't for some reason actually get treated he should be excluded from the final evaluation. Indeed, this is what quite a number of randomized evaluations have done.

However, we have to ask the question: "Was it random that some of those in treatment schools did not get treated?" Are those who were meant to get treated, but didn't, likely to be different in any way from the rest of the children? Think about the reasons why children did not get treated. What are the characteristics of children for whom these factors are more important?

In what ways might this group be different from the average child?

If the evaluators had simply dropped those in the "treatment schools" who did not get the medicine from the study, would that have given them an accurate estimate of the impact of the program? Would they have overestimated or underestimated the impact of the program?

If the evaluators simply assumed that everyone who was meant to get treated got treated, what would this give them a measure of? What if only a very small percent of people who were meant to get treated actually got treated—would that cause problems for the evaluation in some circumstances? What if most of the people who were meant to get treated got treated—what would the resulting estimate be measuring? Are there circumstances when it would make sense to adjust this estimate for the number of people (in the treatment schools) who actually got treated? How might you go about making such an adjustment?

It has also been the case in a number of studies that those who were assigned to the treatment group, but who were not treated, were grouped with the comparison group. Is this a better alternative?

Evaluation in the Presence of Externalities

Not only do school-aged children account for the bulk of infection, they are even more likely to spread the disease because they are less likely to use latrines and more generally have poor hygiene practices. This means that killing the worms in one child may help break the transmission of the disease and so improve the health of other children. This might happen relatively quickly because worms in water and in the bush can only survive for a relatively short period; in other words, the disease cycle is only maintained if new worms are regularly deposited.

Discussion Topic 3: Randomization with Externalities within a Group

Most of the previous work on evaluating the impact of deworming medication on children's health and school outcomes had ignored the fact that giving medication to one child may benefit another child by reducing their chance of infection.

Do you think that this previous work under- or overestimated the impact of deworming on children's health and education outcomes?

Solution to Evaluation with Externalities When the Externalities Are Within a Group

One way to solve the problem of estimating the impact of a program that involves externalities is to measure the effect at the community level rather than at the individual level. When talking about externalities, economists often use the example of a factory which produces smoke and is unpleasant for the whole community: it causes the washing of the neighbors to get dirty, and potentially causes ill health for many living around the factory. If you are trying to evaluate the benefit of reducing the smoke, you wouldn't just look at the costs and benefits to the factory itself, you would try to assess the benefits for everyone in the community.

In the same way, if there was one school in a village which everyone in the village attended, and villages were far away from each other, it would be relatively easy to design an evaluation that took into account the fact that treating some children in the village might reduce the infection of others. You would simply randomize at the school/village level rather than at the individual level and then measure the health benefits for all children in the village.

However, this is not the situation the evaluators faced in Busia District in Kenya. Instead of living in clustered villages, most people live on their farms which are spread relatively evenly, though one family is still close enough to and likely to infect/be infected by its neighbor. Many will have a choice of which school to attend, and it often happens that children from neighboring houses go to different schools and that even siblings in the same family go to different schools.

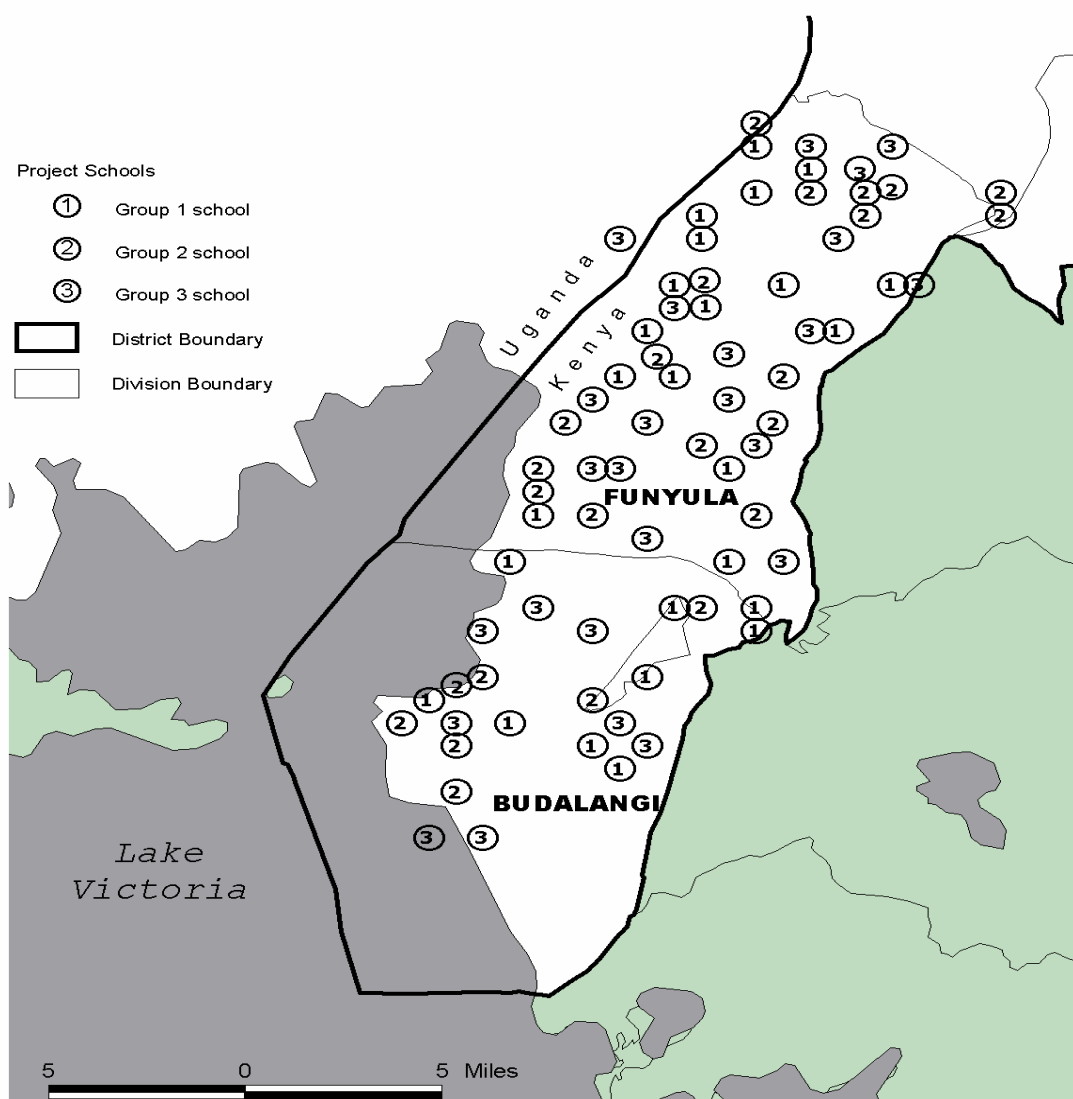

Discussion Topic 4: Randomization with Externalities Between Groups

While the evaluators decided, because of the existence of externalities, to treat each school as a unit, there was still the issue that some children who were not in the “treatment school” might benefit from living near children who were treated.

How could the evaluators deal with this problem?

Look at the diagram on the next page which shows the geographical layout of all the schools. A “1” indicates that the school was in Group 1, a “2” that it was in Group 2, and so on. Does this give you any ideas of how to solve the problem and estimate the true impact of the program?

Primary School Deworming Project Schools, Busia District, Kenya

The GPS locations were collected before May 2000 (when the U.S. stopped intentionally downgrading GPS accuracy), and so may only be accurate to within several hundred meters, (thus one school in this figure appears to be in Uganda). The school that appears to be in Lake Victoria is actually on a small island.
