

	Methodology	Description	Who is in the comparison group?	Required Assumptions	Required Data
Quasi-Experimental Methods	<b>Pre-Post</b>	Measure how program participants improved (or changed) over time.	Program participants themselves—before participating in the program.	The program was the only factor influencing any changes in the measured outcome over time.	Before and after data for program participants.
	<b>Simple Difference</b>	Measure difference between program participants and non-participants after the program is completed.	Individuals who didn't participate in the program (for any reason), but for whom data were collected after the program.	Non-participants are identical to participants except for program participation, and were equally likely to enter program before it started.	After data for program participants and non-participants.
	<b>Differences in Differences</b>	Measure improvement (change) over time of program participants <i>relative to</i> the improvement (change) of non-participants.	Individuals who didn't participate in the program (for any reason), but for whom data were collected both before and after the program.	If the program didn't exist, the two groups would have had identical trajectories over this period.	Before and after data for both participants and non-participants.
	<b>Multivariate regression</b>	Individuals who received treatment are compared with those who did not, and other factors that might explain differences in the outcomes are "controlled" for.	Individuals who didn't participate in the program (for any reason), but for whom data were collected both before and after the program. In this case data is not comprised of just indicators of outcomes, but other "explanatory" variables as well.	The factors that were <i>excluded</i> (because they are unobservable and/or have been not been measured) do not bias results because they are either uncorrelated with the outcome <u>or</u> do not differ between participants and non-participants.	Outcomes as well as "control variables" for both participants and non-participants.
	<b>Statistical Matching</b>	Individuals in control group are compared to similar individuals in experimental group.	<u>Exact matching</u> : For each participant, at least one non-participant who is identical <i>on selected characteristics</i> . <u>Propensity score matching</u> : non-participants who have a mix of characteristics which predict that they would be as likely to participate as participants.	The factors that were <i>excluded</i> (because they are unobservable and/or have been not been measured) do not bias results because they are either uncorrelated with the outcome <u>or</u> do not differ between participants and non-participants.	Outcomes as well as "variables for matching" for both participants and non-participants.
	<b>Regression Discontinuity Design</b>	Individuals are ranked based on specific, measureable criteria. There is some cutoff that determines whether an individual is eligible to participate. Participants are then compared to non-participants and the eligibility criterion is controlled for.	Individuals who are close to the cutoff, but fall on the "wrong" side of that cutoff, and therefore do not get the program.	After controlling for the criteria (and other measures of choice), the remaining differences between individuals directly below and directly above the cut-off score are not statistically significant and will not bias the results. A necessary but sufficient requirement for this to hold is that the cut-off criteria are strictly adhered to.	Outcomes as well as measures on criteria (and any other controls).
	<b>Instrumental Variables</b>	Participation can be predicted by an incidental (almost random) factor, or "instrumental" variable, that is uncorrelated with the outcome, other than the fact that it predicts participation (and participation affects the outcome).	Individuals who, because of this close to random factor, are predicted not to participate and (possibly as a result) did not participate.	If it weren't for the instrumental variable's ability to predict participation, this "instrument" would otherwise have no effect on or be uncorrelated with the outcome.	Outcomes, the "instrument," and other control variables.
Experimental Method	<b>Randomized Evaluation</b>	Experimental method for measuring a causal relationship between two variables.	Participants are randomly assigned to the control groups.	Randomization "worked." That is, the two groups are statistically identical (on observed and unobserved factors).	Outcome data for control and experimental groups. Control variables can help absorb variance and improve "power".
