Abstract

We evaluate the impacts of a randomized job fair intervention. The intervention generates a rich set of interactions, but few hires. However, the fair causes both firms and workers to invest more in search; this improves employment outcomes for less educated job-seekers. Through a unique two-sided belief-elicitation, we show that firms and workers respectively have inaccurate beliefs about the distribution of skills and the difficulty of getting jobs. This suggests that, beyond directly slowing down matching in the labour market, search frictions can impose a second, understudied cost: to entrench inaccurate beliefs, further distorting search strategies and labour market outcomes.

1 A matching experiment

Matching frictions may prevent the efficient allocation of workers across firms, sectors and industries. The costs from this misallocation are likely to be large, especially in developing countries undergoing profound economic transformations (Bryan and Morten, 2019; Hsieh, Hurst, Jones, and Klenow, 2019). However, the precise channels through which matching frictions make it difficult for firms to hire the right workers or for workers to find the right firm are not well understood.

In this paper, we provide new experimental evidence on the distortions generated by matching frictions in a fast-growing developing economy (Alfonsi, Bandiera, Bassi, Burgess, Rasul, Sulaiman, and Vitali, 2020; Abebe, Caria, Fafchamps, Falco, Franklin, and Quinn, 2021). In particular, we focus on the high costs that firms and workers have to bear to meet each other. These costs can have a direct effect on hiring and on job-finding, resulting in a lower probability of well-matched workers and firms meeting one another.¹ In addition, by reducing the exposure of firms to workers and of workers to firms, these costs can entrench inaccurate beliefs about the fundamentals of the labour market – e.g. beliefs on the distribution of job-seekers’ ability. These inaccurate beliefs, in turn, are likely to distort key job-search and recruitment decisions, resulting in fewer and poorer matches. Our central contribution is to shed light on this little-explored second channel – through an experiment that provides a large one-time reduction in the cost of worker-firm meetings, and through a novel survey that captures workers and firms’ beliefs about the labour market.

Our evidence comes from a country that is undergoing a rapid economic transformation: Ethiopia. Similar to many other fast-growing economies in Sub-Saharan Africa, Ethiopia is witnessing the expansion of non-traditional economic sectors, sustained workforce growth, a strong build-up of secondary education, and swift urbanization. In this context, deep changes in market fundamentals may require workers and firms to update their beliefs. At the same time, workers and firms have to pay substantial costs to acquire information, apply for suitable jobs, or to post vacancies and screen candidates (Abebe, Caria, and Ortiz-Ospina, 2021). These costs make it harder to develop accurate beliefs about the labour market.

We evaluate the impacts of reducing these meeting costs by inviting to a job fair a

¹ Eeckhout (2018) summarises some of the key theoretical literature. Additionally, recent structural work in both developed and developing countries consistently detects the presence of meaningful labour market search costs (DellaVigna, Lindner, Reizer, and Schmieder, 2017; Van den Berg and van der Klaauw, 2019; Abebe, Caria, and Ortiz-Ospina, 2021).

sample of young job-seekers and of medium-to-large formal employers. At the fair, workers can meet several employers at a low marginal cost, and employers can easily talk to many potential young recruits. As a result, meeting costs are low and each side of the market has the opportunity to gather a large amount of information about the other side. Our research design has several key features that enable us to fully explore the implications of the matching frictions we study. First, we randomize participation among firms as well as workers, which allows us to test for frictions affecting both employers and job-seekers. Second, we collect information about job interviews and offers arising as an immediate consequence of participation in the fairs, as well as detailed data on firms' and workers' labor market expectations, search strategies, and market outcomes over time. This allows us to test for immediate as well as delayed effects of participation on firms and workers. Third, we invite representative samples of young unemployed workers and of formal firms to participate in the fairs (subject to several eligibility criteria, discussed shortly). This increases the external validity of our findings.

We show that the fairs generate few direct hires (one for every 12 firms that attended), but they lead to a change in search strategies and an increase in search effort among both firms and job-seekers. Specifically, after the fairs, firms increase the amount they spend on advertising positions and job-seekers increase the frequency of their visits to job boards. Moreover, firms decrease their reservation quality for workers (shifting towards less-educated ones) and job-seekers reduce their reservation wages. The effects on job-seekers are concentrated among those without tertiary education, whose employment prospects improve significantly as a result (permanent employment rates double and formal employment rates increase by almost 50 percent).

By means of a simple theoretical framework, we show that the impacts of the intervention are consistent with firms and job-seekers acquiring valuable information at the fairs that helps them to update their priors and correct misperceptions about market fundamentals. In particular, we demonstrate that if prior to the fair firms had unrealistically high expectations about the quality of available candidates and job-seekers had too high expectations about the salaries on offer, increasing search effort and reducing reservation quality/wages is a rational response.

In light of this hypothesised mechanism, we returned to the field following the initial experiment to collect more data on beliefs about the labor market. Specifically, we ran a unique survey administered to both sides of the market, using a new sample of firms and young job-seekers – each side selected respectively during hiring and during job search. This survey enables us to measure carefully a set of beliefs that are central to the

matching process, and may be impacted by participation in a job fair, but that have not yet been documented in the literature – for example, firms’ beliefs about workers’ ability, conditional on observable characteristics. Further, since we simultaneously observe representative samples of both sides of the market, we can contrast beliefs with actual data on the true distributions. Our aim in returning to the field was two-fold. First, we aimed to test whether overoptimism is an equilibrium feature of the labour market – and, through that, to understand whether our job fairs corrected misperceptions, or introduced them. Experiments are typically not suitable to reach such conclusion, since they rarely have access to representative samples of both workers and firms. Second, we wanted to shed light on the sources – i.e., the specific incorrect beliefs about market fundamentals – of the unrealistic expectations we had observed in this market.

The belief-elicitation exercise shows clear evidence of misperceptions on both sides of the labour market. Firms overestimate the ability of job-seekers. Job-seekers have overly optimistic beliefs about their prospects of obtaining higher-paid professional jobs given their qualifications. Importantly, we also show that workers have relatively accurate beliefs about facts that are easy to observe (for example, beliefs about wages across occupations). This suggests that while market participants value and acquire relevant publicly available information, the natural interaction between firms and young job-seekers in the labour market is insufficient for participants to learn key parameters of the matching process that are observed through direct interactions (e.g., the ability of workers). We therefore conclude that the increased pessimism caused by the job fairs likely corrected misperceptions, rather than introducing them, by allowing both sides of the market to acquire an unusually large amount of information about each other. Crucially, updating these distorted beliefs has economically meaningful consequences, as indicated by the strong impacts on search behaviour and the improved employment outcomes of less educated job-seekers generated by the treatment.

Our paper makes two key contributions. First, we offer unique evidence that both firms and workers hold inaccurate beliefs about fundamental aspects of the labour market. Most importantly, we show that both firms and workers suffer not merely from a problem of information asymmetries but from a deeper misperception of the distribution of characteristics among other market participants. By contrast, models of search and matching typically assume that market participants are uncertain about the skills of a specific job-seeker, or the competitiveness of a specific vacancy, but are aware of the distributions from which agents are drawn (Rogerson et al., 2005; Terviö, 2009; Wright et al., 2021). As a result, previous empirical work on market beliefs has mostly generated insights on uncertainty about the characteristics of specific individuals (Bassi and Nansamba, 2021;

Carranza et al., 2021; Abebe et al., 2021). In this paper, we show that firms and job-seekers make decisions on the basis of information that is limited in a more fundamental sense. In doing so, we also provide direct evidence on the beliefs of both firm managers and job-seekers. Evidence on the labour market beliefs of firm managers is particularly scarce. Further, while previous work has often been unable to measure the accuracy of labour market beliefs relative to comparable empirical moments, our simultaneous survey and belief-elicitation exercise enables us to compare beliefs to true empirical values. These unique features allow us to show that firm managers hold beliefs that are substantially inaccurate, and that this has important implications for behaviour in the market².

Second, we show that these mistaken beliefs can be corrected through a simple job fair { and that this triggers changes in search behaviour that lead to better employment outcomes for job-seekers. In other words, our evidence suggests that distorted beliefs persist { at least in part { because workers and firms have relatively little contact. This contributes to a recent literature studying the effects of over-optimism among job-seekers in low-income settings. Banerjee and Sequeira (2021) show that workers are over-optimistic about the probability of finding a job, and that this over-optimism persists due to the spatial distance between workers and firms³. Revising these beliefs causes them to lower their reservation wages and changes the scope of their job search, with no net effect on employment rates. Bandiera et al. (2021) find that matching workers with firms causes workers to revise beliefs downwards and to search less, leading to lower employment rates. We contribute to this literature by establishing that over-optimism among job-seekers can lead them to under-invest in job search and hurt their employment prospects. We find that { for the group with the greatest misperceptions, who update their reservation wages the most { the intervention leads to more search and considerably better employment outcomes⁴. This finding relates to a similar literature from high-income settings, which finds that over-optimism can delay exit from unemployment (Spinnewijn, 2015; Krueger and Mueller, 2016; Mueller et al., 2021); we contribute to this literature by providing

² Our findings complement the results in Abebe et al. (2021), who show that firm managers make biased forecasts about the results a recruitment intervention, and of Caria and Falco (2021), who present lab-experimental evidence that small-firm managers are excessively concerned about worker trustworthiness.

³ Other recent papers showing evidence for over-optimism among job-seekers in developing countries include Alfonsi et al. (2020) and Groh et al. (2015).

⁴ Experimental evidence from van der Klaauw and Ziegler (2021) shows that speeddates with temporary employment agencies in the Netherlands leads workers to search harder and reduce reservation wages. Unlike ours, the effect on overall employment rates of updating beliefs is ambiguous in their setting.

complementary evidence from a low-income context without unemployment insurance⁵. Crucially, we add to this literature by showing that firms too have incorrect beliefs | a point that is not explored in these related papers.

2 The study population

We work in a rapidly growing urban center in a low-income setting, where frictions are likely to be prevalent in the labor market. Addis Ababa, capital of Ethiopia, is a good choice because it combines these characteristics with the additional feature that, at the time of our study, the main avenue through which firms advertise openings is through job-vacancy boards located in the center of the city. While the purpose of these boards is to facilitate job search, they nonetheless entail sizeable transaction costs { especially for job-seekers, who must incur substantial transport costs to visit, and then need to spend considerable time visually scanning the boards to identify suitable openings.

Screening by firms is also challenging, given the limited information that can be extracted from the CVs of young labor market entrants (Abebe et al., 2021). Like many growing cities in the developing world, Addis Ababa has recently experienced a large increase in the number of available jobs, coupled with high in-migration flows. This makes it hard for firms and job-seekers to have accurate beliefs about the distribution of wages, employment opportunities, and workers' abilities. All these features suggest that job fairs are a promising intervention in this context.

2.1 Surveying job-seekers

The job fair intervention reported in this paper draws on the same sampling frame as Abebe et al. (2021) and was partially run alongside it. The study involves a representative sample of young educated job-seekers in Addis Ababa. To select our sample, we first define geographic clusters using enumeration areas from the Ethiopian Central Statistical Agency (CSA).⁷ Our sampling frame excludes clusters within 2.5 kilometres of the center of Addis

⁵ These findings contribute to a broader body of knowledge about the impacts of changing workers' information set on their labour market choices and search strategies (Bassi and Nansamba, 2021; Beam, 2016; Jensen, 2012)

⁶ Abebe et al. (2021) report two parallel field experiments: a transport subsidy to visit job boards, and a workshop intervention to help job-seekers to signal their cognitive and non-cognitive skills to employers.

⁷ CSA defines enumeration areas as small, non-overlapping geographical areas. In urban centers, these typically consist of 150 to 200 housing units.

Ababa and clusters outside the city boundaries. Clusters are selected at random from the sampling frame. To minimize potential spillover effects across clusters, we impose the condition that directly adjacent clusters cannot be selected together.

In each selected cluster, we used door-to-door sampling to construct a list of all individuals who: (i) are aged between 18 and 29 (inclusive); (ii) have completed high school; (iii) are available to start working in the next three months; and (iv) are not currently working in a permanent job or enrolled in full time education. We randomly sample individuals from this list to be included in the study. The lists include individuals with different levels of education. We over-sample individuals with post-secondary education to ensure that they are sufficiently represented in our sample.

All randomly selected individuals were contacted to establish their willingness to participate in the study and be interviewed. We completed baseline interviews with 4,388 eligible respondents. We attempted to contact individuals by phone for at least a month (three months on average) and dropped individuals who could not be reached after at least three attempts. We also dropped any individual who had found a permanent job at the time of baseline and had been in this job at least six weeks. Finally, we dropped individuals who had migrated away from Addis Ababa during the phone survey. In all we were left with 4,059 individuals included in our experimental study. Of these 1006 were invited to the jobs fairs. Another 2226 were involved in the experimental interventions discussed in [Abebe et al. \(2021\)](#), while 823 remain in the control group.

We collected data through both face-to-face and phone interviews. We completed baseline face-to-face interviews between May and July 2014 and endline interviews between June and August 2015. Information was collected on the socio-demographic characteristics of study participants, their education, work history, finances, and their expectations and attitudes. We also kept in touch with all study participants by phone throughout the duration of the study, at which time we administered a short questionnaire on job search and employment⁸.

We have low attrition: 93.3% of baseline respondents were re-interviewed at endline. Few covariates predict attrition and we are unable to reject a joint F -test that a range of covariates have no effect on attrition (see Appendix Table B.9 in the Online Appendix). However, we do find that the individuals invited to the job fairs are slightly more likely to respond to the endline survey. Yet, because attrition is low overall (8% in the control group and 5.6% in the treatment group), we are not concerned that this affects our main

⁸ [Franklin \(2018\)](#) shows that high-frequency phone surveys of this type do not generate Hawthorne effects and do not affect job-seekers' responses at endline.

results. Our key findings are robust to bounding our estimates using the method of Lee (2009). Attrition in the phone survey is also low; for example, we were still able to contact 90% of the respondents in the final month of the study⁹.

2.2 Surveying firms

We surveyed 498 large firms in Addis Ababa. These firms were sampled so as to be representative of large employers in the city, stratified by sector. All major sectors in the economy are covered, including construction, manufacturing, banking and financial services, hotels and hospitality, and other professional services. To sample firms, we first compiled a list of the largest 2,178 firms in Addis Ababa. Since no firm census exists for Ethiopia, we rely on a variety of data sources, including lists of formal firms maintained by different government ministries. In all, we gathered data from more than eight different sources. For the manufacturing sector, we rely on a representative sample of large firms that took part in the Large and Medium Enterprise surveys conducted by the Central Statistics Agency (CSA). For other sectors we requested lists of the largest firms from the government agency in charge of that sector. Whenever information on firm size is available, we impose a minimum size cut-off of 40 workers.

We draw the firms in our sample using sector-level weights to reflect the number of employers in that sector in the city. We construct these weights using representative labour-force data.¹⁰ The firms are, on average, large by Ethiopian and African standards. The mean number of employees per firm is 171.5 workers. This masks considerable heterogeneity, particularly in the 'Tours & Hospitality' sector which is dominated by small hotels and restaurants; when this sector is excluded, average firm size is 326 workers. Detailed information on firms' total employment is given in Table 1, excluding casual daily laborers. On average, firms report employing 34 casual laborers per day.

The firms in our sample are growing in size and looking to hire new workers. At baseline, the median number of workers that a firm expects to hire in the next 12 months amounts to 12% of its current workforce. The median rate of hiring is highest (16%) among service sector firms, which are also the most likely to come to the job fairs. The most common types of workers whom firms expect to hire are white-collar workers, usually

⁹ Appendix Figure B.1 shows the trajectory of monthly attrition rates over the course of the phone survey.

¹⁰ Table B.6 in the Online Appendix shows the number of firms surveyed in our sample, divided into five main categories. Column (2) provides weighted percentages obtained by applying the inverse of the weights used to sample the firms. For instance we surveyed NGOs ('Education, Health, Aid') relatively infrequently because of the large number of NGOs in the data.

requiring university degrees. For details, see Appendix Table B.4.

3 Experimental design

3.1 Randomization to the job fair

We assign treatment of job-seekers to the job fairs by geographical cluster, after blocking on cluster characteristics (see Abebe et al. (2021) for further details). The sample is balanced across all treatment and control groups, and across a wide range of outcomes { including baseline outcomes that are not used in the stratified randomization procedure. We present extensive balance tests in Appendix Table B.1. For each baseline outcome of interest, we report the p-values for a test of the null hypothesis that we have balance between treatment and control groups. We cannot reject the null for any of variables that we study.

We assign firms to either a treatment group or a control group using block-level randomization techniques suggested by Bruhn and McKenzie (2009). Firms in the treatment group are invited to attend the job fairs; control firms are not. The following method is used to block firms for sampling. Firms are first partitioned into five main industries (see Appendix Table B.6). Within each industry, firms are partitioned into blocks of four nearest neighbors on the basis of their Mahalanobis distance over a set of baseline variables.¹¹ We then randomize the firms in each block into two groups of two firms: one firm is invited to the first day of the job fair; the second is invited to the second day (see below for details); and the other two are assigned to serve as controls. Given the relatively small size of the firm sample, we use a re-randomization approach to ensure balance on a set of baseline covariates listed in Table B.2.

3.2 Implementation of the job fairs

We invited treated job-seekers and treated firms to attend two job fairs. The first fair took place on October 25 and 26, 2014. The second fair took place on February 14 and

¹¹ The variables used for blocking are listed in Appendix Table B.7.

¹² Following the recommendations of Bruhn and McKenzie (2009), we control for these covariates in our estimation, as well as for the baseline covariates used to construct the randomization blocks. Details of these variables and how they are defined are contained in our detailed pre-analysis plan. Simulations show that, with this sampling strategy, we have 78% power to detect a small treatment effect of 0.2 standard deviations at a significance level of 0.05%.

15, 2015. We run two fairs to increase the chance that each job-seeker and firm is able to participate in at least one of them. The job fairs were held at the Addis Ababa University campus, a central and well-known location. To minimize congestion, each job fair lasted two days and a randomly selected half of the firms and job-seekers were invited to attend on each day. The firms that were invited to attend on Saturday 25 October were then invited to attend on Sunday 15 February; firms invited for Sunday 26 October were invited for Saturday 14 February. In contrast, job-seekers invited to attend on the Saturday of the first fair were also invited to attend on the Saturday of the second fair; job-seekers invited for the Sunday of the first fair were invited for the Sunday of the second fair. This ensures that, in each job fair, job-seekers are exposed to a different pool of firms, and that firms are exposed to a different pool of job-seekers¹³.

During each fair, job-seekers and firms are free to interact as they see fit. Each firm sets up a stall before the job-seekers arrive. These stalls are typically staffed by the firm's HR team who bring with them printed material advertising the firm. In a typical interaction, a job-seeker approaches the stall of a firm and asks questions about the firm and its vacancies. The firm's HR staff is then free to check his or her CV and to ask about the job-seeker's skills and work experience. If the job-seeker looks suitable for one of the firm's vacancies, the firm invites her or him for a formal job interview a few days after the job fair.

To avoid self-selection out of the sampling frame, we do not restrict invitations to the fairs to currently unemployed job-seekers, or to firms that have open vacancies at the time of the fair. Of our initial sample of job-seekers, only about 8% had permanent jobs by the time of the first job fair, and thus most job-seekers were still searching for work. Similarly, most firms were hiring at the time that the job fairs were held. 89% hired at least one worker in the year of the study and, on average, firms hired four workers in the month after the job fairs and 52 workers in the year of the fairs.

In total, we invited 1,007 job-seekers and 248 firms to attend the fairs. Both job-seekers and firms were contacted by phone, were given some information about the nature of the fairs, and had the opportunity to ask questions. Among firms, 170 attend at least one job fair, which represents quite a successful take-up rate of 68.5%. Of the firms that do not attend the fairs, 12% say it is because they do not have an open vacancy at the

¹³ Weekend days are selected to maximize the opportunity for both firms and job-seekers to attend. In preliminary discussions with firms, we realized that most would be unable to take time off from daily activities to attend during the week, but they were interested in attending on a weekend. Similarly, many job-seekers in our sample work in casual jobs and are more likely to be unavailable during the week. Since many Ethiopians attend religious services on the weekend, we set a long enough time window for job-seekers to be able to attend.

time. The remaining firms tend to cite logistical issues or previous commitments. Only 13 firms respond that they would not find the job fair useful.¹⁴

Of the 1007 invited job-seekers, 606 attend at least one fair, a 60% take-up rate. The most common reason that job-seekers give for not attending the fairs is that they are busy during that particular weekend. This reason is given by 226 job-seekers in the first fair and 229 job-seekers in the second. Other reasons include not being able to take a new job (9 job-seekers at the first fair and 83 at the second) and finding the venue of the fair hard to reach (31 respondents for the first fair and 25 for the second).

Two baseline characteristics predict higher attendance by job-seekers: search effort at baseline; and whether the job-seeker uses a school certificate during job search. It follows that job-seekers who attend the fairs are, if anything, more active and organized in their job search. Those who attend are also more likely to have a university degree or diploma, but this is not statistically significant. Taken together, this evidence provides reassurance that results are not driven by negative selection of job-seekers coming to the fairs.

3.3 Matching at the fairs

At the beginning of each fair, we give job-seekers a list of all the firms invited. In the second fair, we also give job-seekers the list of all vacancies, and we give firms a list of all job-seekers invited to the fairs, with some information about their education and past work experience. We then ask firms to list up to 10 job-seekers with whom they would like to talk at the job fair. After collecting the list of requested meetings from each firm, we post them on a board at the fair.¹⁵

In order to increase match efficiency and avoid congestion at the fairs, we create a list of 15 recommended meetings that we give to each job-seeker at the beginning of the fair. Of the 15 firms on the recommended list, 10 are selected using a Gale-Shapley Deferred Acceptance algorithm described below ([Gale and Shapley, 1962](#)); the other five are selected at random. The order of presentation on each list is similarly randomized. We tell job-seekers that these are the firms they should talk to during the fair. Each firm similarly receives a personalized list showing the names of all the job-seekers who have been recommended to meet that firm. The recommendations are based on information about firms' vacancies that we obtain through a phone survey shortly before the fair.

¹⁴ In Appendix Table B.8, we run a descriptive regression to explore correlates of firm attendance at job fairs.

¹⁵ Given the logistics of collecting lists of names from more than a hundred employers, the lists were posted a few hours after the beginning of the fair.

The purpose of the Gale-Shapley algorithm is to suggest sensible matches for these vacancies, given baseline characteristics of both job-seekers and firms. Indeed, not all job-seekers are qualified for certain positions, and not all firms can attract the best job-seekers. To avoid firms and job-seekers wasting time in unsuccessful meetings, we seek to pair those firms and job-seekers who, given the distribution of firms and job-seekers at the fair, stand a higher chance of leading to a hire. To this end, we start by constructing a synthetic ranking of all vacant positions for each job-seeker, and similarly a synthetic ranking of all job-seekers for each firm. The rankings of job-seekers by firms are constructed using lexicographic preferences over: (i) whether the job-seeker held a previous occupation that matches that of the vacancy; (ii) the job-seeker's educational qualification for the job; and (iii) the job-seeker's years of wage employment. The rankings of job-seekers vary across firms. For the job-seeker's rankings of vacancies, we use a simple ranking over the advertised wage. This means that, for the purposes of forming recommendations, all job-seekers synthetically rank vacancies in the same way.

These rankings are not intended to represent literally the true preferences of all participants over all possible matches. Indeed, gathering information on all these preferences would have been logistically impossible in the allotted time and any attempt to impose such a ranking burden on job-seekers or firms would undoubtedly have reduced substantially the participation in the experiment. Rather, the rankings are intended to provide a fast way of improving on random encounters at the fairs that takes into account the heterogeneous set of vacancies and job-seeker skills that are present at the fair. After creating a ranking of job-seekers for each vacancy and a ranking of vacancies for each job-seeker, a Gale-Shapley algorithm is used to match job-seekers and firms. Specifically, the algorithm generates a single set of matches; we then iterate the algorithm 10 times, requiring a different set of recommended matches each time¹⁶. This generates the 10 recommended matches mentioned above; to this list, we then add five random matches.

Figure 1 illustrates the outcome of the matching algorithm. Each point represents a stable match recommended by the algorithm. The figure shows which combinations of firm rankings and job-seeker rankings generated these recommended matches. The graph provides a visual illustration that the algorithm worked well in the sense of generating matches between firms and job-seekers who are, on the basis of job-seeker skills and experience, reasonably suitable for each other. Note the substantial mass at the bottom-left of the graph. It shows that, for those firms paying higher wages, the algorithm recommend matches that provide a reasonable occupational fit. For example, for top

¹⁶ We implement this requirement by taking the matches recommended in iteration t and placing those matches at the bottom of the firms' and job-seekers' rankings in iterations $s > t$.

100 firms in the job-seekers' ranking, the median match is to a job-seeker with a firm ranking of just 14, that is, a job-seeker ranked quite high according to our synthetic firm preferences.

4 The effects of the fairs

In this section, we document the impacts of the job fairs on employment outcomes and search behaviour { both at the level of the job-seeker and at the level of the firm. We begin by presenting evidence on hiring that took place at the fairs and in their immediate aftermath. We then present impacts on employment and search outcomes at endline (six months after the second fair). We also present evidence on the trajectories of impacts based on a high-frequency survey conducted between baseline and endline.

We measure employment outcomes through data on job interviews, offers, hiring, and employment in different types of jobs. To test for impacts on search behaviour, we estimate treatment effects on reservation wages and on the search strategies used by firms and job-seekers at endline (e.g., amount spent on advertising vacancies, amount of time spent looking for jobs). It should be noted that impacts on search behaviour are more likely to be observed if a direct effect on hiring is absent or weak: if treated job-seekers find a job and firms fill their vacancies as a direct outcome of the fairs, they have little cause to revise their expectations and search strategy.¹⁷

4.1 Immediate impacts: Hiring at the job fairs

The fairs generated rich interactions between firms and job-seekers. 454 job-seekers (75% of those attending) interacted with at least one firm at the job fair, either through an informal interview or an in-depth discussion with a recruiter. This finding is particularly strong among participants who benefited from the matching algorithm treatment (as discussed below). In total, we record 2,191 contacts between firms and job-seekers.

The interactions at the fairs resulted in 105 formal job interviews conducted at participating firms in the immediate aftermath (the finding is based on a phone survey conducted

¹⁷ The pre-analysis plan that we led for this experiment can be found at <https://www.socialscisearch.org/trials/1495>. Most pre-specified outcome families are presented in the order in which they appear in the PAP. Those that are not documented here in detail can be found in the Online Appendix.

immediately after each fair).¹⁸ Further, these 105 interviews are concentrated on 67 job-seekers only, representing 11% of those attending the fairs. These interviews led to 76 offers (made in the immediate aftermath of the fairs) to a total of 45 job-seekers, which represents a healthy conversion rate of one offer for each 1.4 interviews (and compares favourably with the open-market rate of 1.9). Contrary to what one might expect in a job fair for educated job-seekers, offers were disproportionately made to less-educated applicants.¹⁹ A large majority (81%) of offers, however, were rejected. The offer rejection rate is particularly high among less educated job-seekers: 85% for applicants with a high-school diploma compared with 71% for those with tertiary education. Only 33% of offer recipients with a high-school diploma accepted one of their offers. We view these findings as prima facie evidence of a mismatch between workers' expectations and what firms are willing to offer. Overall, we find that the fairs had little immediate impact on hiring by treated firms (Appendix Table B.11 and B.12).

In Appendix A, we test whether the limited impacts of the fairs on hiring may be due to the market being too thin (too few high-quality matches available), or to problems of congestion and mis-coordination during the fairs. We have evidence against both hypotheses. First, we document that the firms attending the fairs had a large number of open vacancies at the time of the event and the occupational composition of those vacancies exhibits considerable overlap with the distribution of occupations desired by invited job-seekers. Second, using dyadic data on firm-worker interactions, we show that our stylized matching algorithm was useful in identifying matches that were deemed worth pursuing by market participants. Specifically, we show that our synthetic rankings strongly predict both requested meetings and actual meetings. The fairs thus appear to have reached their objective of facilitating meetings between job-seekers and the firms that suited them best. This reassures us that our setup managed to minimise wasteful interactions and potential congestion.

4.2 Endline impacts on search, hiring and employment

In this section, we examine the impacts of the intervention at endline (six months after the second fair). We report impacts on firms and workers separately. For the latter, we also leverage a high-frequency survey to study the trajectories of impacts in the months following the job fairs. Overall, we find clear evidence that both firms and job-seekers

¹⁸ This implies a rather low conversion rate of 1 interview for each 20.9 contacts established at the fair (in the open market, we estimate that job-seekers get an interview every 3.5 applications made).

¹⁹ 55 offers (72%) went to job-seekers with at most a high-school diploma, even though they represented a minority of the job-seekers attending.

increase their search effort as a result of being invited to the fairs, and this leads to changes in employment outcomes that are particularly evident for the group of job-seekers that revised their search strategies the most (less-educated workers).

4.2.1 Impacts on firms' search strategies and hiring outcomes

First, we study the impact of the intervention on the search and hiring outcomes of firms measured at endline. To this end, we use an ITT approach with an ANCOVA specification. Following current practice, covariates used for balancing the randomization are included as controls. For each outcome of interest, we estimate regressions of the form:

$$y_i = \alpha_0 + \alpha_1 \text{fairs}_i + y_{i;\text{pre}} + X_{i0} + \epsilon_i; \quad (1)$$

with robust standard errors. Variable $y_{i;\text{pre}}$ is the dependent variable measured at baseline and X_{i0} includes the randomization variables listed in Table 2. In the tables, we show each regression as a row and we report the estimated $\text{ITT}_i(\hat{\alpha}_1)$, the mean of the control group, and the number of observations. We report both p-values and False Discovery Rate q-values, the latter being calculated across the family of outcomes (Benjamini et al., 2006).²⁰

Our first finding is that, as a result of the job fairs, firms invested more in worker search and recruitment. Our regression estimates, presented in Table 3, show that treated firms are six percentage points more likely to advertise new vacancies in the last 12 months, relative to a control mean of about 79%. They are also 12 percentage points more likely to advertise for professional positions, relative to a control mean of 60%. Firms are also almost 10 percentage points more likely to advertise their vacancies on the job boards, relative to a control mean of 33 percent. All three effects are statistically significant after controlling for multiple hypothesis testing. This suggests that the intervention leads both firms and job-seekers to search more intensely through the main channels available to

²⁰ Throughout this paper, we report the average treatment effect of the job fairs. As outlined in the pre-analysis plan, our study was designed to enable us to estimate separately an effect of the fairs both with and without additional information revelation about workers' abilities. Since we found no direct effect of the fairs on hiring for either treatment arm, and the experimental information revelation was designed specifically to improve direct hiring at the fairs, we took the decision to pool the treatment arms. This improves the precision of our null estimates of the direct effects of the fairs.

²¹ Throughout the analysis, we distinguish between professional workers and non-professional workers. 'Professional workers' refers to traditional notions of 'white-collar employees': typically those with some degree or diploma working in relatively highly skilled positions. For manufacturing firms, 'non-professional workers' refers mostly to production workers; for service-based firms, these include mostly workers dedicated to client services (tellers, waiters, receptionists etc).

them at the time of the study.²²

Our second finding is that firms reorient their hiring away from highly educated workers, in particular for professional positions. In other words, they lower the reservation quality of their hires. Among firms that hire above the median number of professional workers { a pre-specified dimension of heterogeneity { we find that, beyond raising recruitment investments, the firms also (i) significantly reduce the proportion of professional workers with degrees by about 7 percentage points (relative to a control mean of 72 percent), (ii) reduce hiring by an average of 17 workers (over a control mean of 62 workers), and (iii) reduce overall firm size.²³ These results are consistent with the fact that firms at the job fairs did not extend interviews to workers with degrees (as discussed above). Importantly, they are also consistent with the finding { discussed in the next section { that firms in this labour market have overly optimistic beliefs about the ability premium of highly educated workers.

The changes in firms' recruitment strategies have only small effects on aggregate hiring outcomes at endline. We find a small but significant increase in unfilled vacancies over the 12 month period from baseline to endline (in Panel A of Table B.10). We find no impact on the time taken to fill open positions or on firms' reported costs of recruitment. We find no significant impact on the number of people hired in the last 12 months, the hiring of job candidates with a degree, or hiring on a permanent contract (Panel B of Table B.10).²⁴ This is perhaps not surprising, given that our sample is composed of large firms that hire on average 56 new workers per year. In these firms, changes in recruitment practices may take a longer time to affect the overall composition of the workforce.

4.2.2 Impacts on job-seekers' search strategies and employment outcomes

Next, we examine the effect of the treatment on job-seekers' search, reservation wages, and employment outcomes. The specification we estimate is the same as equation 1, but we now focus on job-seekers rather than firms. To account for the fact that job-seekers were randomized to treatment according to their enumeration area of residence, standard errors are clustered by enumeration area. We report both conventional p -values and False

²² We do not find significant heterogeneity in these impacts. However, effects on recruitment appear to be larger among firms that did not hire many young people at baseline (Table B.19). This result is consistent with a learning story, as those firms likely have noisier and more inaccurate priors about young people in the labour market.

²³ Results (i) and (ii) are presented in Table B.23 in the Appendix, result (iii) is shown in Table B.22.

²⁴ Similarly, we find no impact on the firms' overall workforce composition (Appendix Table B.13), overall turnover and employee growth (Appendix Table B.14), and general HR practices (Appendix Table B.15).

Discovery Rate q -values.

We have two key findings on how the intervention impacts the search behaviour of job-seekers, which mirror the ones on the behaviour of firms. First, the treatment increases job-seekers' search effort. This is reflected in a higher number of visits to job boards at endline as shown in Panel A of Table 4: treated job-seekers report roughly three more visits to the job boards, relative to a control mean of 15. We can plot the trajectory of the effects on search over time, using high-frequency phone call survey conducted between baseline and endline. Figure 2 shows that the probability that a job-seeker visits the boards goes up by about 8.3 percentage points (26 percent) in six weeks following the first job fair.²⁵ Since the job boards are the main source of information on vacancies, this represents a sizeable increase in their effort to search for employment.

Second, the fairs reduce reservation wages, bringing them more in line with market wages. We show these results in Panel A of Table 4. In column (1), we see that treatment results in a significant 7 percent reduction in endline reservation wages. Further, to test whether treatment brings reservation wages more in line with market conditions, we construct a 'wage mismatch' variable equal to the absolute difference between the log of the reported reservation wage, and the log of the average wage earned by a worker with the job-seeker's skill and education. We present data on the mismatch between market wages and reservation wages in Table 5, and treatment effects on wage mismatch in column (2) of Table 4. We find that treatment reduces the wage mismatch by a significant 4 percent.²⁶

Turning to the impacts of the fairs on the employment outcomes of job-seekers, we find that the effects are concentrated among the least educated ones, who experience a large increase in employment quality due to the intervention. In Panel B of Table 4 we disaggregate treatment effects by whether or not the respondent has more than secondary education. Among the less educated job-seekers, we document an increase of 6 percentage points in the probability of having a permanent job relative to a control mean of just 6 percent at endline { i.e., a doubling of the probability of permanent employment. We similarly find an increase in the probability of having a formal job by 5 percentage points

²⁵ Specifically, we estimate this difference in probabilities using a Linear Probability Model in an AN-COVA specification, in which we regress job search on treatment, baseline search status and a sector of baseline balancing variables. We cluster at the level of individual job-seekers, and show both point estimates and 90% confidence intervals; we do this both by regressing on fortnight dummies, and by imposing a quadratic shape.

²⁶ Additional treatment effects on employment outcomes, job amenities, and job search at endline are presented in Appendix Tables 4, B.2, and B.3.

relative to a control mean of about 11 percent { i.e., a 45% improvement²⁷. It is important to note that less educated workers are also the ones that experience the most significant changes in the search strategies, driving the average impacts discussed above (i.e., higher search effort and lower reservation wages²⁸). This is consistent with the hypothesis that changing search strategies in light of the information acquired at the fairs leads to better labour-market outcomes for job-seekers.

5 A dynamic model of search under distorted beliefs

The results in section 4 show that the experience of attending the fairs { rather than the successful creation of a match { persuaded each side of the market to revise their search strategies. On the one hand, firms hired very few job-seekers through the fairs, yet the fairs caused firms to invest more in worker search and recruitment. On the other hand, the fairs caused job-seekers to expend more effort on search, and to lower their reservation wages, and to be more likely to find jobs six months later. This immediately implies that each side of the market received an important shock to their beliefs.

In this section, we present a stylised theoretical framework that helps us to interpret the results outlined above, and offers an explanation for the observed changes in search behaviour after the fairs. Specifically, the model formalises the notion that firms and job-seekers held beliefs that made them overly optimistic about the possibility of finding a good match, given their existing investments in search. The model illustrates how a sobering information shock can cause an increase in search effort. We consider a firm trying to fill a single vacancy (we later discuss how the same framework also usefully captures the search problem of a job-seeker). The model incorporates important features observed among surveyed firms { notably, that firms (i) often have a specific notion of a minimum appointable standard when advertising a position, and (ii) seldom hire quickly for an advertised position.

The model firm searches in discrete time (with discount factor $\beta < 1$). In each period that the vacancy remains unfilled, the firm suffers a direct reduction in profit of $\lambda > 0$; this could reflect, for example, the cost of being unable to proceed with a project for want of

²⁷ In the bottom row of Table 4 we report p-values for the null hypothesis that treatment effects are equal across educational categories. The null is rejected for wage mismatch and having a permanent job, and it is close to being rejected ($p < 0.12$) for visiting job board and having a formal job.

²⁸ They reduce their reservation wages by 9 percent as a result of treatment, closing the mismatch between reservation wages and market wages by 7 percent. They increase their visit to the job boards by 4.2 percent, relative to a control mean of 11 visits.

filling the vacancy. In each period that the vacancy remains unfilled, the firm may spend $s > 0$ to generate λ matches with prospective employees, such that λ is Poisson(s). The quality of any given match $x > 0$ is drawn from some distribution $F_x(x; \bar{x})$, where the mean \bar{x} represents the firm's belief about the quality of available applicants. We denote by y the quality of the best match realised in a given period (where $y = 0$ if there are no matches); following [Bobotas and Koutras \(2019\)](#) and [Wilken \(2021\)](#), this best match has CDF $F_Y(y; s; \bar{x}) = \exp[-F_x(y; \bar{x}) \lambda s]$.

Having observed y , the firm decides whether to hire. The firm optimally does this using a cutoff rule, comparing y to some reservation match quality \bar{x} ; thus, the firm hires if $y \geq \bar{x}$ and otherwise prefers to leave the position open. We impose that the firm has some minimum match quality z , implied by the technical requirements of the position; this operates as a lower bound on the firm's choice of \bar{x} . For example, there is a minimum set of technical skills that a crane driver must reach before she can be employed {irrespective of how costly the firm finds it to leave the position vacant.

For simplicity (and following [McCall \(1970\)](#)) we assume that, if the firm hires, the contract is permanent {so that the value of meeting a best applicant with quality $y \geq \bar{x}$ is simply $V(y) = y/(1 - \beta)$. Note that the firm is indifferent between all values of $y \geq [0; \bar{x}]$; therefore, the value to the firm of leaving the position unfilled is defined recursively as:

$$V(0) = \max_{s \in [0; \bar{x} - z]} s + \beta E[V(y | s; \bar{x})]; \quad (2)$$

where

$$E[V(y | s; \bar{x})] = \underbrace{F_Y(\bar{x}; s; \bar{x})}_{\text{Firm does not hire}} V(0) + \int_{\bar{x}}^{\bar{z}} \underbrace{\frac{y}{1 - \beta}}_{\text{Firm hires}} dF_Y(y; s; \bar{x}); \quad (3)$$

and, by the definition of the bounded reservation quality,²⁹

$$\bar{x} = \max[(1 - \beta) V(0); z]; \quad (4)$$

Together, equations 2, 3 and 4 describe the model, and capture its key trade-offs. The firm has two distinct reasons to hire: (i) an extensive margin impact (by hiring, the firm avoids the loss of s), and (ii) an intensive margin impact (by hiring, the firm also gains $y/(1 - \beta)$ in every subsequent period). The firm invests in costly search activities ($s > 0$) in order to increase the number of matches {and, therefore, to improve the expected quality of

²⁹ That is, if the firm were unconstrained, it would set \bar{x} such that $V(\bar{x}) = V(0)$. The firm chooses the greater of this value and the minimum reservation quality, z .

the top candidate.

Depending on the values of the key parameters, this model is capable of generating several different types of behaviour { and, in particular, different comparative statics with respect to firm beliefs about worker quality.³⁰ In Figure 3, we consider a regime with particular relevance to our experimental results, using relatively large values for both β and z .³¹ On the horizontal axis of each panel, we show β with higher values of β to the left, so that a move to the right indicates a more pessimistic firm belief.³² Panel A shows the firm's optimal choice of search effort, s . Panel B shows the firm's reservation quality, \bar{x} ; specifically, it shows both z , as a dotted blue line, and $(1 - \beta) V(0)$, as a dotted red line; the solid black line is therefore the upper envelope. Panel C shows the firm's anticipated probability of hiring, given its beliefs: $\Pr(y \geq \bar{x} | s)$. It is useful to visualise this anticipated probability in order to understand the motivation for the firm's optimal choice of both search effort and reservation quality.

Here, the model demonstrates three distinct regimes. First, on the left of each figure, β is relatively large; here, a 'pessimism shock' (that is, a decrease in β) leads to a decrease in search. This might be understood as the 'safe regime'; because the anticipated probability of finding a suitable applicant is extremely high (Panel C), the decrease in β causes a reduction in search in the current period (Panel A) because, when the pool quality is high and thus the expected value of next period is high, the marginal gain from searching more intensively today is small relative to waiting for a better applicant tomorrow. In this regime, the exogenous minimum quality (z) does not bind: the reservation quality is determined by the option value of leaving the position vacant to 'wait and see' whether a more suitable candidate can be found. In turn, this implies that the value function is continuous at \bar{x} (because $V(\bar{x}) = V(0) = \bar{x}(1 - \beta)$). In the safe regime, a small reduction in the expected pool quality reduces search.

At the other extreme, if β is very small (far right of the figure), the firm lies in an 'exit regime': the effort required to find a suitable candidate is so high that it is optimal not to search at all. In the exit regime, a pessimism shock has no effect at all since the firm has already decided not to search.

Between the two is an intermediate regime that we dub the 'unsafe regime'. The key characteristic of this regime is that β is not low enough as to make search unprofitable, but

³⁰ We solve this model using a standard value function iteration (where we evaluate $E[V(y | s; \bar{x})]$ using a fast Monte Carlo integration). For our numerical implementation, we use the Exponential distribution for x ; that is, we use $F_x(x; \beta) = 1 - \exp(-\beta x)$:

³¹ For this illustration, we use $\beta = 1$, $\beta = 0.95$, $\beta = 50$ and $z = 5$.

³² Specifically, we graph values for β from $\beta = 3$ down to $\beta = 0.5$.

is sufficiently low that the exogenous minimum quality (z) binds on the firm's reservation quality (Panel B). This implies that the value function is discontinuous at \bar{x} : if the firm's top candidate is just below the appointable quality z , the firm suffers a discrete fall in profit compared to a candidate who barely reaches that threshold (formally, $\lim_{x \rightarrow \bar{x}^-} V(x) < V(\bar{x})$). In turn, this implies that the firm anticipates a meaningful probability that it will not hire (Panel C). In this regime, for sufficiently low β , the decrease in β causes an increase in search expenditure. Given the relatively high cost of not filling the position ($\beta \gg 0$), and driven by the firm's growing concern that it will not find a suitable candidate, the pessimism shock makes the firm search more intensely.

We view this intermediate regime as being not only the most interesting, but also empirically the most relevant.³³ The notion of an exogenous minimum candidate quality ($z \gg 0$) is justifiable by technical requirements (as in the example earlier, of a crane driver); it may also reflect organisational constraints, by which firms may face internal morale consequences of hiring underqualified candidates at a posted wage (see, for example, [Breza et al. \(2018\)](#)). The notion of a discrete cost of not filling a position ($\beta \gg 0$) resonates, for example, with 'O-Ring' style production processes ([Kremer, 1993](#)), in which the absence of a worker generates productivity costs for the firm as a whole.

What about unemployed workers? The model discussed above describes a firm searching for a prospective employee. The same stylised setup can readily be understood, *mutatis mutandis*, as describing search behaviour of our job-seekers. In the case of a job-seeker, x and y can be understood as referring to posted wages, and $\beta \gg 0$ can be understood as capturing the disutility from being unemployed (including, for example, facing social pressure from family and friends, needing to impose on the generosity of others for financial and accommodation support, and so on). In the job-seeker context, we can think of $z \gg 0$ as a reference point below which the job-seeker is not willing to shift { driven, perhaps, by the leisure value of remaining unemployed, or by a distaste for low-status work (as documented, for example, by [Groh et al. \(2015\)](#) in Jordan).

In the unsafe regime, the searching-firm model predicts that a pessimism shock (i) increases search effort, and (ii) has no effect on reservation quality { because, in that regime, $\bar{x} = z$. The model makes similar predictions for job seekers: in the unsafe regime, they respond to a pessimism shock by increasing job search and, initially at least, they keep their reservation wage $\bar{x} = z$ unchanged. It is, however, not difficult to imagine a model extension in which z adjusts over time as unemployed workers 'swallow their pride' and settle for a less ideal wage { for example, as a result of liquidity constraints as the

³³ The model is capable of generating other patterns, for other parameter values. For example, for $z = 0$, the firm lies in the 'safe regime' for all β .

unemployed job-seeker exhaust available search funds and family support.

6 Measuring beliefs directly

Our theoretical framework shows { both on the firm side and the job-seeker side { that it is likely that a sobering shock to beliefs will increase search intensity. In this section, we provide empirical evidence showing that workers and firms at the job fairs indeed had over-optimistic beliefs about the quality of a likely match during the intervention. However, this does not establish that over-optimism is a general feature of the labour market we study, as the fairs may have exposed individuals to a negatively selected sample of the other side of the market, or may have inadvertently sent misleading signals (we discuss these alternative explanations in depth in section 6.4). Thus, we returned to the field to collect new data on the beliefs of representative samples of firms and workers and found clear evidence that, in equilibrium, beliefs are indeed systematically inaccurate, on both sides of the market. This is one of the most central findings of this paper. Importantly, it also helps us support the hypotheses that (i) unrealistic beliefs contribute to the low levels of hiring at the job fairs, and (ii) that the downward revision of beliefs caused by the job fairs did bring expectations closer to reality.

6.1 Follow-up survey

Following up on our initial experiment, in 2019 we conducted a new belief-elicitation exercise with firm managers and job-seekers. Since our objective was to understand whether potential misperceptions exist among market participants in the absence of our treatment, we did not go back to the original sample that took part in the experiment but rather surveyed a new representative sample of job-seekers and firms. Specifically, we contemporaneously sampled firms that were advertising vacancies on Addis Ababa's job boards and job-seekers that were looking for vacancies at those job boards³⁴. The survey has three unique features. First, it focuses on a real, well-defined labour market. Second, it elicits beliefs on both sides of the market. While a number of papers study job-seeker beliefs, systematic data on the beliefs of firm managers is rare, especially in developing

³⁴ We interviewed 395 firm managers and 779 job-seekers. We recruited job-seekers between the age of 18 and 29, who had at least a high school diploma. We contacted a random sample of firms that were advertising a position on the job boards or in the newspaper between the end of November and the end of December 2019. We also contacted some of the firms that job-seekers were applying to. In this way, we selected samples of firms and job-seekers that resemble on key dimensions our original experimental participants.

countries. Third, the survey enables us to measure the accuracy of beliefs. In particular, we can contrast firms' answers with the true empirical counterparts obtained from the job-seeker survey and viceversa; this improves over existing studies that elicit beliefs but cannot measure their accuracy.³⁵

The questionnaire for firms carefully elicits firm managers' beliefs about the ability of job-seekers { a key element of the model outlined above. Since our intervention produced very heterogeneous effects by job-seeker level of education, we document expectations with respect to tertiary-educated applicants and high-school graduates separately. Ability is measured as a job-seeker performance on a Raven's test. We took a number of steps to make sure that lack of familiarity with such a test among firm managers would not distort our results. First, we provided the instructions for the test to the firm managers, so that they could familiarise themselves with it. Second, before managers answered the ability questions, we provided them with real statistics on the difference in test score between workers with a high (75th percentile) and an average GPA in our sample. This served the purpose of generating an anchor by giving employers a sense of how test results correlate with an observable characteristic (GPA) commonly used in hiring. In addition to measuring expectations about job-seekers' ability, we also elicited managers' beliefs about the job-seekers' reservation wages and their work experience. The elicitation exercise was incentivised.³⁶

The questionnaire for job-seekers focuses on their beliefs about the distribution of wages across sectors, their reservation wages, and their beliefs about the expected duration of unemployment. We elicited beliefs about the distribution of wages by asking the job-seeker what proportion of jobs currently advertised paid a wage lower than a set of thresholds (from 10,000 ETB to 1,000 ETB per month). Similarly, we elicited reservation wages by asking the job-seeker whether they would accept a job that would pay at least a certain amount. This amount was decreased until we found the wage bracket corresponding to the job-seeker reservation wage. To minimise complexity, we did not incentivise the elicitation of beliefs among job-seekers. Finally, after the belief-elicitation was completed, job-seekers took a 12-item Raven test.

In light of our theoretical model, we use the data from the survey to investigate

³⁵ In addition, our survey focuses on a new sample of market participants as opposed to the original experimental subjects. This has two distinct advantages over working with our original sample. First, attrition after several years may have biased our sample. Second, the subjects that took part in the intervention were exposed to the information they gained at the fairs. Our interest, on the other hand, is in uncovering perceptions biases that may have existed prior to the fair.

³⁶ Participants were told that one of the questions they were asked would be randomly drawn at the end of the survey and they would receive a prize based on the accuracy of their answer.

the hypothesis that firm managers and job-seekers may have distorted perceptions about the quality of available matches. For firm managers, we test this by comparing their perceptions about the quality of job-seekers (i.e., their ability) with the actual distribution of ability in our sample. For job-seekers, we test whether beliefs about the expected duration of unemployment and the quality of available jobs (proxied by wages) align with reality. We also test how their reservation wages compare with prevailing wages.

6.2 Distorted beliefs among firm managers

We find clear evidence of distorted beliefs among firm managers. Our first result is that firm managers overestimate the ability of job-seekers. We asked firms to predict how many questions on a Raven's test a representative individual with high school or tertiary education, respectively, after first asking firms to familiarize themselves with the test. Figure 4 shows that 65% of firms overestimate the average Raven's test scores for workers in the educational category for which they are currently hiring. Firms' average forecast of tests scores is higher than the true average. We find that all of this average overestimation comes from managers overestimating the ability of workers with tertiary education. We show this in Figure B.2 through a series of 'raincloud plots' of manager beliefs, with superimposed vertical lines showing the average job-seeker characteristic. At the same time, we find that firms underestimate the ability of secondary-educated job-seekers. The average secondary-educated job-seeker answers about 5 questions on the Raven test correctly, while the average tertiary-educated job-seeker answers about 5.3 questions correctly. By contrast, the median firm forecasts that secondary-educated job-seekers answer 4 questions correctly, while tertiary-educated job-seekers answer 6 questions correctly. In other words, the true ability premium associated with tertiary education is less than one fourth of what firms expect. Further, the perceived difference between the two groups is twice as large as the difference in Raven performance between individuals at the 75th percentile and at the mean of the GPA distribution { the anchoring information we gave to firms before these forecasts. Overall, almost 75% of firms overestimate the ability of tertiary-educated job-seekers and about 90% of them overestimate the ability premium associated with tertiary education. Because most firms in our sample are trying to hire workers with tertiary education, the average firm in the sample overestimates the ability of the types of worker they are trying to hire as summarised in Figure 4.

Additionally, we find that firms overestimate work experience and reservation wages among tertiary educated job-seekers. More than 75% of managers overestimate the share

of tertiary educated job-seekers who have at least two years of work experience (Figure B.2). The median manager expects about 20 percent of tertiary-educated workers to have two years of work experience, a figure that is almost twice the true proportion. Furthermore, in the survey, we ask firms to indicate the proportion of job-seekers who would accept different wage levels for the most common job available at the firm. Figure 5 shows that firms overestimate the reservation wages of tertiary-educated job-seekers across occupations { but most starkly with respect to professional roles. Finally, as was the case for ability, the patterns for secondary-educated workers are reversed: firms underestimate both their work experience (e.g. Panel B of Figure B.2) and their reservation wages (Figure B.3).

In sum, firms on average overestimate the ability and work experience of the jobseekers they are trying to hire. This shows unequivocally that firm beliefs are inaccurate in equilibrium. Furthermore, our findings on firm beliefs can help explain why hiring at the job fairs was modest: firms were disappointed by the tertiary-educated job-seekers they met, while they underestimated the ability and reservation wages of the secondary-job-seekers, so the offers they extended to this group were rejected. This interpretation is further supported by clear evidence that past experience is highly sought after by firms. First, the most common reason firms report for not hiring more at the fair is 'insufficient work experience' (34% of firms)³⁷. Second, past experience is the strongest predictor of a meeting request according to our dyadic analysis of firm-requested meetings (and the effect is strongest among workers with tertiary education, in line with our story)³⁸. Overall, the evidence is consistent with the idea that the fairs gave firms an opportunity to acquire information and negatively update their beliefs by interacting with a large number of candidates. This led, in turn, to the observed revision in their search strategies as predicted by the model.

6.3 Distorted beliefs among job-seekers

On the job-seeker side, we have clear evidence of over-optimism about available opportunities among workers with lower levels of education. First, job-seekers with less than

³⁷ Other common reasons relate to the perceived expertise of workers or poor interview performance (see Table B.17). Educational mismatch plays a role, but is certainly not the most important factor.

³⁸ We apply the same dyadic regression approach as in equations (5) and (6) and report the results in Table B.18. The dependent variable is $isrequest_{fj}$, a dummy equal to one if firm f requested a meeting with job-seeker j , using a centralized meeting-request algorithm that we offered to firms at the fair. Regressors include job-seeker and firm characteristics. The results are not driven by firms who sought experienced job-seekers outside the fair: even firms willing to hire graduates without work experience at baseline are more likely to request experienced job-seekers at the fair.

tertiary education overestimate the probability of attaining permanent employment within 12 months. This is shown in Figure 7, which compares the expected likelihood of finding a permanent position according to job-seekers in our most recent survey with data on the actual likelihood of getting a permanent position in the control group of our experimental sample.³⁹ For example, 55% of job-seekers with only a high-school diploma expect to find a job with a permanent contract in less than 1 year. In reality, only 5.8% of our experimental sample found a permanent job within 1 year. Furthermore, when asked about job-seekers in the same age cohort with the same education and work experience, respondents expect 30% of them to find a permanent job within one year. This suggests that job-seekers with a high-school diploma are not only over-confident about their own ability relative to the rest of their cohort, they are also over-optimistic about the prospects of the average individual like themselves

Second, in contrast to job-seekers' misperceptions about their likelihood of attaining employment, we found that their beliefs about the quality of available jobs (proxied by wages) are well-aligned with reality. When asked about average wages in different occupations, the answers respondents provide closely track prevailing wages in different sectors (Figure B.5 and B.4).

Third, turning to reservation wages, we found that 70% percent of job-seekers with only high-school and no permanent work experience would reject a job paying 2000 ETB per month. Yet 44% of jobs in the same market for that occupation and level of experience pay less than 2000 ETB per month. This finding was also evident in the data collected at the time of the experiment, where we recorded reservation wages among job-seekers that were strongly misaligned with the wages that firms at the fairs were expecting to pay.⁴⁰ Such misalignment is consistent with the high offer-rejection rate by less educated job-seekers at the fairs discussed above. In contrast, Table 5 shows that job-seekers with tertiary education that were invited to the fairs have reservation wages that are well within the

³⁹ Since we only interview job-seekers once, we do not have data on the length of their unemployment spell in the most recent survey and we have to resort to the experimental sample. We believe this provides a valid benchmark. First, the two populations were selected using similar screening criteria based on age and education. Thus, when we re-weight by observables to ensure comparability between the two samples, there are no qualitative changes in our findings. Second, although the two samples were interviewed a few years apart, aggregate labour market conditions are not significantly different between the two periods. Third, to drive the observed divide between more educated job-seekers and less educated ones, labour market conditions should have varied differentially for different groups of workers. We have no evidence of that occurring.

⁴⁰ As shown in Table 5, job-seekers invited to the fairs with a high-school diploma and no experience report a median reservation wage of 1,300 Birr per month. This stands in sharp contrast to the median salary of 855 Birr that firms report offering to high-school graduates with no work experience.

boundaries of what is available in the market.⁴¹

Finally, our data allows us to dig deeper into the biases that may lead job-seekers to have over-optimistic beliefs about their likelihood of attaining employment and their excessive reservation wages. We have already shown that the latter is not due to mistaken beliefs about how much different jobs pay. An alternative hypothesis is that they may be targeting jobs that are beyond their reach (i.e., they have high reservation wages because they expect to have high chances of getting well-paid jobs). In other words, they overestimate their probability of employment in 'good jobs'. We find evidence in support of this hypothesis. The data shows that job-seekers with secondary education often seek positions for which firms largely hire tertiary educated job-seekers (and which, therefore, they are unlikely to get). Figure 6 shows this clearly. A large proportion of job-seekers with secondary education (Panel A) seek employment in professional categories such as 'Technicians and professionals' and 'Services and sales workers', even though firms offer relatively few opportunities in those roles to job-seekers with secondary education. This may explain why job-seekers with secondary education rejected job offers at the fairs: those offers were overwhelmingly for the less-professional occupations and without permanent contracts; over-optimism may have caused them to hold out for relatively unattainable positions. Conversely, the search efforts of job-seekers with tertiary education (Panel B) are better aligned with available opportunities: the occupations they seek (e.g., 'Technicians and professionals') are the most commonly offered to tertiary graduates by employers in our sample.

Why are low-educated job seekers targeting jobs that are generally out of reach for them? Are they misinformed about the kinds of profiles firms are looking for in professional jobs, or over-confident about their own ability relative to other people like them? Our beliefs data suggest that it is the former: these job seekers are misinformed about the likelihood that someone with their profile will get a professional job. We asked job-seekers who were targeting high-skilled jobs {managerial, technical or professional jobs, who they thought would eventually get that job. Among job seekers who have not completed a tertiary degree, fewer than 20% believe that the vacancy will eventually be filled by someone with a tertiary degree. A similar number think that a degree is a minimum requirement for the job. In reality, among firms in the beliefs' data, 71% of high-skilled vacancies have degrees as a minimum requirement, while 74% eventually went to someone with a degree. Half of the job seekers think that no previous work experience is a requirement

⁴¹ On average firms report paying recruits with a university degree around 4,500 Birr per month, which is well above the median reservation wage of 2,500 Birr reported by university graduates without experience at the fairs. Only 10% of tertiary graduates in our sample have a reservation wage above the average wage paid for employees with their qualifications.

for a high-skilled job, and 36% think that the job will go to someone without any formal work experience. In reality, firms report that only 16% of high-skilled jobs require no formal experience, 59% of jobs require two or more years of experience.

On the other hand, job-seekers with secondary education have fairly accurate beliefs about the distribution of wages in specific occupations (Figure B.5; the same is true for job-seekers with tertiary education, as shown in Figure B.4). If anything, they tend to overestimate the proportion of jobs at the bottom of the wage distribution. High reservation wages among high-school graduates are thus plausibly linked to having an unrealistic occupation target, rather than an inaccurate perception of the wages paid in the market.

In sum, over-optimistic beliefs about the likelihood of employment and high reservation wages among high-school graduates are plausibly linked to having an unrealistic occupational targets, rather than an inaccurate perception of the wages paid in the market. The information gathered at the job fairs, where workers had an opportunity to learn what profiles firms were actually looking for, gave them a chance to update their priors, triggering the observed change in their search strategies, and improving their employment outcomes.

6.4 The follow-up survey and alternative interpretations of the job fair

The follow-up survey shows that both firms and job-seekers hold unrealistic beliefs about each other. This immediately provides a plausible explanation for the failure of the job fairs to create any meaningful number of new hires { notwithstanding the success of the fairs in encouraging job-seekers and managers to meet. Together with our model, it can also explain the changes in search and employment behaviour observed in the aftermath of the job fairs: both sides of the markets observed some truth about the fundamentals of the labor markets, and that caused them to update to their beliefs in line with reality.

This evidence on beliefs provides key evidence for our preferred interpretation of the experimental findings, against two alternative explanations. The first explanation is based on selection. Suppose that firms and jobseekers have correct beliefs, but the fairs expose them to non-representative samples of market participants. For example, the firms that attend the fairs may have more competitive vacancies than the average firm on the market. If workers do not take this selection into account, they may incorrectly become more pessimistic about the probability of securing a job. The second explanation is based

on unintended signals: workers and firms may mis-interpret the invitation to the fairs as a negative signal about the state of the labour market. Alternatively, in a case when the low matching rate at the fairs was due to poor logistics (e.g. workers had a hard time locating the right employers, etc...), participants may wrongly attribute the low matching rate to labour market fundamentals.

Under all of these stories, the job fairs generate a misleading signal about the market that moves participants' priors away from the truth. Our descriptive evidence on selection and matching at the fair gives us initial evidence against these explanations. We showed that the samples invited to the fairs were fairly representative and that take-up was not highly selected. Further, in Section A.1 and Section A.2 we presented results showing that meetings were positively selected on expected match quality, helping us rule out the poor logistics story. For these reasons, we conclude that attendees came to the job fairs with over-optimism that was underpinned by the same incorrect beliefs that we document in our follow-up survey; the more pessimistic outlook of attendees after the job fairs is consistent with their having corrected these misperceptions. In sum, the results presented in this section further support our preferred alternative interpretation of the experimental result | that both workers and firms were overoptimistic and the fairs helped to correct this.

7 Conclusion

We run a novel experimental job fair, with a unique dual randomization { both on the side of job-seekers and of participating firms. The job-seekers invited to the fairs are representative of the type of young job-seekers whom firms usually hire, and participating firms are a representative sample of large employers. We facilitate interactions between job-seekers and firms by providing information about job-seekers' education and firms' vacancies, and by suggesting matches based on a Gale-Shapley algorithm. We study both the direct effects of the treatment on job-seekers' and firms' outcomes, and subsequent effects on both learning and search.

We find that the fairs generate a rich set of interactions between job-seekers and firms, and that the matching algorithm is successful in increasing the efficiency of the matching process. However, the direct impact of the treatment on employment outcomes is very limited: only 14 hires are made as a direct consequence of two job fairs that bring together hundreds of firms and job-seekers. Crucially, however, we find clear evidence of delayed effects of treatment, as both firms and job-seekers appear to learn from the experience at

the fairs: they change their expectations accordingly and adjust their search strategies. Treated job-seekers with at most a high-school diploma had misaligned reservation wages prior to treatment; after the fairs, they search harder and experience a significant increase in their probability of obtaining a formal job. Treated firms increase their efforts to search, both for professional positions and through advertising at the job boards. Follow-up survey work with similar job-seekers and firms confirms both that firms have an inaccurate perception of the skill premium of job-seekers with tertiary education, and that job-seekers have overly optimistic beliefs about the probability of obtaining professional jobs given their qualifications.

The main contribution of our paper is to show that both firms and job-seekers hold inaccurate beliefs about market fundamentals { that is, that labour market participants suffer not merely from a problem of information asymmetries, but from a deeper misperception of the distribution of characteristics among other market participants. Although we find that the fairs did not directly facilitate matches { suggesting that reducing the costs of face-to-face meetings alone is not sufficient to overcome matching frictions in this context { we do find that the fairs serve to reduce these deep misperceptions. These results show that active labour market policies that increase contact between job-seekers and firms { such as job fairs, and including many other classes of policy intervention { are likely to generate important learning effects on both sides of the market.

Test High=Post (p)	0.268	0.051	0.118	0.718	0.018	0.116	0.577

Notes: Each row reports a separate regression. `Wage mismatch' refers to the absolute difference between the worker's reservation wage (in logs) and the expected wage for a worker of that skill/education level (in logs). For each regression, we report the estimated ITT from participating in the job fair (disaggregated, in Panel B, by whether the worker has post-secondary education or merely high school). Standard errors are reported in parentheses. In the bottom row, we report p-values for a test of the null hypothesis that the effect of treatment is equal between high-school and post-secondary sub-samples.

Table 5: Mismatched expectations: Reservation wages of workers before the fairs, wages offered at the fairs, and endline employment outcomes (Medians)

	Education of worker			
	High-school	Vocational	Diploma	Degree
Panel A: Workers' reservation wages and firms wages for jobs offered at the job fairs				
Worker reservation wages before fairs				
With Experience (13%)	1500	2000	2000	3000
Without Experience (87%)	1300	1500	1600	2500
Firm wages for positions at fairs				
Require Experience	1588	1900	3250	5685
Don't require Experience	855	1018	1168	3500
All Jobs	973	1500	2900	4500
Panel B: Workers' employment outcomes at endline				
Worker employment rates at endline				
All jobs	50%	46%	43%	69%
Permanent jobs	6%	17%	19%	35%
Worker wages at endline by experience				
With Experience	1450	1450	1743	3000
Without Experience	975	1400	1350	2100
All Experience levels	1000	1400	1500	2300
Worker wages at endline by job type				
Permanent work	950	1400	1662	2373
Non-permanent work	1000	1400	1200	2291

Notes: This table describes self-reported reservation wages (for jobseekers) using phone survey data in the weeks just prior to the first job fair, offered wages at the job fair (for firms), and endline wages (for jobseekers), disaggregated by types of worker and type of job.

Figures

Figure 1: Output of the matching algorithm

Notes: This figure illustrates the outcome of the matching algorithm. Each point represents a stable match recommended by the algorithm. The figure shows which combinations of firm rankings and job-seeker rankings generated these recommended matches. The graph provides a visual illustration that the algorithm worked well in the sense of generating matches between firms and job-seekers who are, on the basis of job-seeker skills and experience, reasonably well-suited to each other.

Figure 2: Impacts on Job Search by Fortnight

Notes: This figure shows the probability, for each fortnight, that treated job-seekers visit the job board, relative to job-seekers in the control group. Fortnight 0 is when the first job fair was held; the second fair was held in fortnight 8. We estimate the difference in probabilities using a Linear Probability Model in an ANCOVA specification, in which we regress job search on treatment, baseline search status and a vector of baseline balancing variables. We cluster at the level of individual job-seekers, and show both point estimates and 90% confidence intervals; we do this both by regressing on fortnight dummies, and by imposing a quadratic shape.

Figure 3: Model predictions

panel b: reservation quality

panel c: anticipated probability of hiring

This figure shows the key predictions of our dynamic search model. Specifically, it shows numerical results obtained by a value function iteration (and using a standard Monte Carlo integration). We use the Exponential distribution: $F_x(x; \lambda) = 1 - \exp(-\lambda x)$, and set $\lambda = 1$, $\beta = 0.95$, $\gamma = 50$ and $z = 5$. The horizontal axis shows values for θ from $\theta = 3$ down to $\theta = 0.5$. The panels respectively show (i) the firm's optimal search effort, s (Panel A), (ii) its reservation quality, \bar{x} (Panel B), and (iii) the resulting probability of hiring, $\Pr(y \geq \bar{x} | s)$ (Panel C). (Panel B shows both \bar{x} , as a dotted blue line, and $(1 - \beta) V(0)$, as a dotted red line; the solid black line is therefore the upper envelope.)

Figure 4: Distribution of manager's forecast error on jobseekers' average Raven's test score

Notes: The forecast error is computed as the difference in percentage points between a manager's belief about the average score of workers in the educational category (high school or tertiary education) most sought after among current vacancies open at the firm, and the actual average score of workers in that educational category.

Figure 5: Firms' beliefs about the distribution of job-seekers' reservation wages: Tertiary-educated job-seekers

Notes: These figures show the distribution of r_m beliefs about job-seekers' reservation wages. In each graph, we show this at five wage points: in each case, we show the distribution of r_m beliefs (using thin bars to show the 10th and 90th percentiles, thick bars to show the 25th and 75th percentiles, and a star symbol to show the median). The coloured lines show the true proportion of our job-seekers with a given reservation wage (where the shaded area represents the 90% confidence interval for the proportion).

Figure 6: Distribution of occupation sectors
panel a: high-school graduates

panel b: tertiary graduates

Note: This figure shows the distribution of (i) the proportion of total jobs in the most common occupations in each firm, and (ii) the sector of the job most commonly looked at by job-seekers in the last week. We show both bars for the five most common sectors for the firm side. We report D_{KL} , the Kullback-Leibler distance from the distribution of jobseeker sectors to the distribution of firm occupation sectors.

Figure 7: Jobseekers' expectations of finding a job with a permanent contract in the next 12 months

Note: `Expectation: Self' refers to jobseekers' stated probabilities that they will be employed with a permanent contract in the next 12 months, as measured in our 2019 follow-up survey. `Expectation: Other' refers to jobseekers' stated probabilities that others like them will be employed with a permanent contract in the next 12 months, as measured in our 2019 follow-up survey. `Actual' refers to the actual proportion of jobseekers who found a job with a permanent contract, using our original survey data.

Online Appendix

A Robustness Checks

A.1 Was the market at the job fairs too thin?

One possible explanation for this small direct effect is the market at the job fairs was too thin: there were too few high-quality worker-firm matches available. We present evidence against this hypothesis both from the jobseeker and the firm side. First, we investigate whether the jobs on offer were too few or did not match jobseekers' interests. To study this issue, we use data that was collected from participating firms prior to arriving at the fairs. Firms were to provide a roster of all their open vacancies at the time of the fairs.⁴² The average firm at the fair had two vacancies open and was looking to hire seven workers. 70% of participating firms had at least one vacancy. In total, there were 711 vacancies and 1,751 jobs available at the fairs. The occupational composition of the vacancies exhibits considerable overlap with the distribution of occupations desired by jobseekers invited to the job fairs. It is therefore unlikely that firms did not have enough vacancies of the kind that jobseekers wanted.

Second, we investigate whether jobseekers were negatively selected and hence firms were reluctant to hire them. To explore this possibility, we compare the jobseekers who attended (about 60% of those invited) to those in the full sample, which is near-representative of educated young jobseekers in Addis Ababa at the time of the study. In Appendix Table B.5 we regress attendance at the fairs on a rich set of baseline characteristics. We find no evidence suggesting that observably weaker candidates are more likely to attend the fairs: education and current employment do not significantly predict attendance. The only two robust predictors of attendance are instead associated with a positive motivation to work: attendance is higher among those jobseekers who search

⁴² We define a vacancy as an open position for a specific occupation. Firms first produced a list of vacancies (e.g. a firm could report that they were both looking for clerical workers and for drivers) and, then, for every vacancy, they reported the number of workers they were planning to hire in that position.

the most at baseline and who produce a formal certificate to employers⁴³. Further, in the second job fair, we showed firms the list of qualifications of jobseekers at the fair and asked them whether they were interested in interviewing some of them. Most responded positively and provided the names of several candidates of interest to them. Across both fairs, firms report meeting 20 jobseekers on average. We can therefore rule out that firms were in principle uninterested in the jobseekers that attended the fairs.

A.2 Did the fairs suffer from congestion and mis-coordination?

Since both employers and jobseekers were interested in each other and willing to interact, could the small direct effect of the fairs be due to congestion and miscoordination? That is, could the effect be explained by firms and jobseekers having wasted their time and effort talking to the wrong people? To investigate this possibility, we test whether the jobseeker-firm pairs that met are those that were most suitable for each other, given the mix of employers and jobseekers at the fairs. We use two types of variables to assess mutual suitability: the synthetic rankings, and the proposed matches that we suggested to participants. The two ranking variables are $Rank_{kj}$, which is firm f 's ranking of jobseeker j , and $Rank_{kf}$, which is jobseeker j 's ranking of firm f . The two proposed match variables are: $Gale_Shapley_{fj}$, which is equal to 1 if jobseeker j and firm f were recommended to each other by our Gale-Shapley algorithm, and $Random_{fj}$, which is 1 if jobseeker j and firm f were randomly recommended to each other by us. If firms and jobseekers are able to engage in promising interactions, we expect participants' rankings to predict who wishes to meet with whom and who actually meets whom. If our matching algorithm was capable of identifying promising matches instead of random matches, we expect meetings and willingness to meet to be predicted by $Gale_Shapley_{fj}$ but not by $Random_{fj}$.

To test these hypotheses, we estimate two dyadic regression models:

$$y_{fj} = \alpha_0 + \alpha_1 Rank_{kj} + \alpha_2 Rank_{kf} + \epsilon_{fj}; \quad (5)$$

$$y_{fj} = \alpha_0 + \alpha_1 Gale_Shapley_{fj} + \alpha_2 Random_{fj} + \epsilon_{fj}; \quad (6)$$

where y_{fj} is either $request_{fj}$, a dummy equal to one if firm f requested a meeting with jobseeker j , or $meet_{fj}$, which equals one if firm f and jobseeker j actually met. Standard errors are clustered two-way at the level of the firm and jobseeker (Cameron, Gelbach, and Miller, 2011).

We report estimates in Table A.1, using the jobseekers and firms who attended the fairs. We find that the synthetic rankings predict both requested meetings and actual meetings. The effects are large and significant. Moving from the highest to the lowest rank is associated with an almost 100 percent decrease in the probability of a requested meeting, and about a halving of the probability of an actual meeting. We interpret these

⁴³ Invitees already in permanent employment at the time of the fairs are slightly less likely to attend. But the effect is unlikely drive our results: 4% of those attending the fairs have a permanent job compared to only 5.6% of the total sample.

results as showing that the fairs are effective in bringing together jobseeker-firm pairs who { at least on the basis of observable characteristics } value each other. Algorithmic recommendations are also shown to have a strong predictive power: matches suggested by our algorithm are about 200 percent more likely take place than non-suggested matches. In contrast, the coefficient on randomly suggested matches is small and never significant. This contrast suggests that our stylized matching algorithm was useful in identifying matches that were deemed worth pursuing by market participants. The fairs thus appear to have reached their objective of facilitating meetings between jobseekers and the firms that suited them best.

This interpretation is supported by comparing the application-to-interview and interview-to-offer rates at the fairs versus in the open market. First, in the open market, job-seekers secured an interview for every 3.5 job applications, an offer for every 1.9 interviews, and a job for every 3.3 interviews over the period between the baseline and endline surveys. This implies that contacts with employers at the fair (20 on average) were much less likely to result in an interview than a formal job application. The contrast is particularly striking for highly educated job-seekers, who tend to do better in the labour market but did particularly poorly at the fair. Second, the 1.4 conversion rate of interviews into offers compares favorably to the 1.9 conversion rate observed outside the fairs. Third, the conversion of interviews into jobs is much lower at the fair: one job for 7.5 interviews instead of 3.5 outside the fairs. A large majority (81%) of offers made in the aftermath of the fairs were rejected. To verify these findings, we conducted a phone survey of firms immediately after each job fair. Appendix Tables B.11 and B.12 show the immediate impact on overall hiring and the type of job candidate hired, respectively. These results confirm that the fairs had no significant impact on short-term hiring by treated firms.

Appendix Table A.1: Dyadic regressions: Rankings, matches and meetings

	Requested (1)	Actual (2)	Requested (3)	Actual (4)	Requested (5)	Actual (6)
Firm ranking of workers	-0.006 (.001)	-0.002 (.0006)			-0.006 (.001)	-0.001 (.0006)
Worker ranking of rms	-0.002 (.002)	-0.001 (.002)			-0.002 (.002)	-0.001 (.002)
Algorithm suggestion			.020 (.007)	.015 (.006)	.014 (.006)	.014 (.006)
Random suggestion			.0006 (.006)	.003 (.007)	.0009 (.006)	.003 (.007)
Const.	.027 (.004)	.012 (.004)	.012 (.001)	.006 (.001)	.026 (.004)	.011 (.003)
Obs.	27778	27778	27778	27778	27778	27778
Effect size: max to min rank	.024	.006			.024	.005
Algorithm = Random			.029	.14	.123	.178

Notes: This table reports the estimates of equations 5 and 6. The highest ranked worker and firm are assigned a value of zero. Lower ranks correspond to higher numbers. Standard errors are corrected for two-way clustering at the level of the worker and at the level of the firm. The last row reports the p-value of an F-test of the hypothesis that the effect of the algorithmic and the random suggestion are the same.

Employment at the time of the job fair				
Permanent Job			-0.161** (0.0646)	-0.160** (0.0692)
Any Job			-0.00143 (0.0338)	-0.00576 (0.0335)
Constant	0.748*** (0.253)	0.398*** (0.0376)	0.631*** (0.0270)	0.664** (0.263)
Observations	1,006	1,006	1,006	1,006
R-squared	0.018	0.045	0.007	0.063

Note: This table reports regression coefficients from a Linear Probability Model, in which we regress attendance at the fairs on a rich set of baseline characteristics; we provide robust standard errors in parentheses. We find no evidence suggesting that observably weaker candidates are more likely to attend the fairs: education, gender, and current employment do not significantly predict attendance. The only two robust predictors of attendance are instead associated with a positive motivation to work: attendance is higher among those job-seekers who search the most at baseline and who produce a formal certificate to employers.

Appendix Table B.6: Main industry classifications

Main Industry	Frequency	Percent
Tours-Hospitality	92	18.7
Finance, Services, Retail	102	20.7
Education, Health, Aid	104	21.1
Manufacturing	126	25.6
Construction, Mining, Farming	69	14.0
Total	493	100

Note: This table shows the initial partitioning of firms into five main industries prior to randomisation.

Appendix Table B.7: Blocking variables for the rm randomisation

variable	definition	source (question number)
plc	Firm is a private limited company	g3 = 3
total_n_all	Total number of pay-roll employees at the rm	l1_1_n
prop_p	Proportion of workers who are professionals	l1_5_n/l1_1_n
ed.deg	Number of workers at the rm with a degree	rowtotal (l1_19_1)=rowtotal(ed_total)
to_all	Rate of turnover in the last year	rowtotal (l2_1_)=total_n_all
formal_adv	Firms advertise when recruiting for jobs	l4_2_1=1 or l4_2_2=1
fairs	Firms expressed interest in attending a job fair	l4_31
hire_all	Rate of new hiring in the last year	rowtotal (l3_2_)=total_n_all

Note: This table defines the variables used for blocking for rm randomisation.

Degree	-0.024 (0.017)	Married	-0.015 (0.017)
Worked (7d)	-0.015 (0.016)	Years since school	0.000 (0.0027)
Searched job (7d)	0.008 (0.014)	Lives with parents	0.008 (0.015)
Female	0.029** (0.013)	Ever had permanent job	0.002 (0.019)
Respondent age	0.000 (0.0027)	Searched job (6m)	-0.020 (0.017)
Born outside Addis	0.031** (0.015)	Amhara	0.000 (0.014)
		Constant	0.061 (0.060)
Average Attrition	6.7%	R-squared	0.012
Observations	1,827	F-test (treatment)	4.320
F-test (covariates)	1.130	p-value (treatment)	0.038
p-value (covariates)	0.320		

Note: This table reports regression results from a Linear Probability Model, in which the dependent variable is a dummy for whether a job-seeker attrited between baseline and endline; parentheses show heteroskedasticity-robust standard errors.

Appendix Table B.10: Firm recruitment in the last year

Outcome	Estimated ITT	Control Mean	Observations
Panel A: Short term recruitment outcomes			
Time taken to fill professional vacancies	-2.344 (1.986) [.658]	24.11	338
Time taken to fill non-professional vacancies	0.724 (1.751) [.909]	15.66	109
Number of interviews per position (professional)	0.312 (2.355) [.909]	8.818	361
Pay per recruitment (professional)	746.7 (1030.791) [.909]	2818	382
Pay per recruitment (non-professional)	-437.8 (320.543) [.658]	1259	406
Unfilled vacancies	0.601 (.247)** [.101]	0.859	305
Panel B: Characteristics of workers recruited			
Number of new hires for the year (professional)	-1.604 (2.688) [1]	11.73	472
Number of new hires for the year (non-professional)	-9.704 (7.283) [1]	44.64	472
Did firms mostly hire people with degrees (professional positions)?	-0.00800 (.041) [1]	0.574	473
Percentage of new hires hired in permanent positions (non-professional)	-0.00900 (.03) [1]	0.892	337
Percentage of new hires hired in permanent positions (professional)	-0.00800 (.031) [1]	0.876	308

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q -values are reported in square brackets, corrected for the tests conducted within each panel.

Appendix Table B.11: Impacts on firm hiring after job fairs

Outcome	Estimated ITT	Control Mean	Observations
Number of vacancies	0.169 (.266) [1]	1.115	422
New Hires	-0.671 (.866) [1]	3.907	422
Hiring shortfall	-0.0160 (.034) [1]	0.0290	193
Unfilled vacancies	0.380 (.785) [1]	2.143	422

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q -values are reported in square brackets.

Appendix Table B.12: Impacts on firm hire quality after job fairs

Outcome	Estimated ITT	Control Mean	Observations
Permanent workers hired	0.0200 (.049) [1]	0.336	422
Days taken to recruit for position (avg)	0.311 (1.386) [1]	11.75	190
Starting salary of new recruits (avg)	-673.9 (636.454) [1]	1031	160
Workers with degrees hired (%)	-0.0430 (.044) [1]	0.237	422

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q -values are reported in square brackets.

Appendix Table B.13: Firms' total workforce composition

Outcome	Estimated ITT	Control Mean	Observations
Total number of employees	-18.38 (16.581) [.847]	350.5	473
Proportion of professional workers on permanent contracts	0.0190 (.019) [.847]	0.908	462
Proportion of non-professional workers on permanent contracts	0.0280 (.02) [.67]	0.896	408
Average starting salary (professional)	-53.52 (235.925) [1]	4280	454
Average starting salary (non-professional)	102.9 (126.66) [.847]	1059	400
Proportion of professional workers with degree	-0.0570 (.027)** [.366]	0.645	461
Proportion of workers with post-secondary education (non-professionals)	0.0370 (.027) [.67]	0.355	407
Average worker is not under-qualified in any of the worker categories	0.00300 (.038) [1]	0.752	473

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q -values are reported in square brackets.

Appendix Table B.14: Impacts on firm turnover and employee growth

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Firing rate (professionals)	0.00400 (.004) [1]	0.00600	458
Firing rate (non-professionals)	0.00300 (.005) [1]	0.0130	319
Quit rate (professionals)	0.00800 (.02) [1]	0.143	458
Quit rate (non-professionals)	0.0250 (.037) [1]	0.134	320
Employee growth rate	0.0170 (.016) [1]	0.0140	472
Employee growth rate (professionals)	-0.0140 (.03) [1]	0.0310	467

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Table B.15: Impacts on firm human resources policies and attitudes

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Firm reports HR problem	0.0820 (.037)** [.217]	0.752	473
Uses incentives in HR	0.0390 (.043) [.588]	0.595	473
Firm estimate of a fair wage	201.2 (312.897) [.592]	5463	452
Uses short term contractors	0.0480 (.045) [.588]	0.479	473
Uses performance rewards (professionals)	-0.0300 (.045) [.592]	0.545	473
Uses performance rewards (non-professionals)	-0.0740 (.045)* [.417]	0.562	473
Retrains poor performers	0.0390 (.04) [.588]	0.719	473

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Figure B.1: Attrition rate from the Phone Survey by Month

Notes: This figure shows the trajectory of monthly attrition rates over the course of the phone survey. Attrition is defined as failure to complete one interview.

Appendix Table B.16: Impacts on firm growth and productivity

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Firm is for-profit	-0.0140 (.011) [1]	0.867	471
Sales Revenue (last year)	-17575 (23388.044) [1]	144370	331
Value Added	-15491 (11969.701) [1]	80851	327
Profit (inferred)	6026 (4791.574) [1]	12975	326
Self-reported profit	1853 (7175.053) [1]	29626	313
Capital stock	60034 (123774.721) [1]	185398	279
Investment (12 months)	-6452 (5920.8) [1]	20147	398
Sales per worker	-57.12 (76.278) [1]	604.5	330
Value added per worker	19.45 (28.102) [1]	220.3	326

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Table B.17: **Firms' reasons for not hiring workers they met at the fairs**

Main self-reported reason	Percent
Insufficient work experience	34.38
Wrong expertise	7.03
Wrong educational qualifications	23.44
Poor performance at the interview	7.03
The candidates we wanted were hired by other firms	3.91
Poor references	2.34
Salary disagreement	2.42
Workers were not interested or did not apply	1.61
Workers arrived late	1.61
Firm did not have vacancies at the time of the fair	3.23
Other	10.48

Appendix Table B.18: Dyadic regressions: Firm requests to meet workers as function of worker characteristics

	(1)	(2)	(3)	(4)
	Firm requested to meet worker			
Worker has some permanent work experience	0.0173*** (0.00657)		0.0151** (0.00652)	0.0132** (0.00617)
Worker is recent graduate	0.00185 (0.00379)	0.00185 (0.00379)	-0.000304 (0.00450)	0.00153 (0.00479)
Worker has certificate with application	0.00190 (0.00273)	0.00190 (0.00273)	0.00136 (0.00285)	0.00182 (0.00286)
Worker has postsecondary education	0.00729*** (0.00257)	0.00729*** (0.00257)	0.00783*** (0.00270)	0.00808*** (0.00279)
Permanent work experience * fresh graduate	-0.00610 (0.00948)	-0.00610 (0.00948)	-0.00317 (0.01000)	-0.000833 (0.0107)
Permanent work experience * Highschool only	-0.0180*** (0.00663)	-0.000785 (0.00421)	-0.0162** (0.00679)	-0.0139** (0.00652)
Permanent work experience * postsecondary education		0.0173*** (0.00657)		
GS- algorithm suggested match			0.0256*** (0.00805)	0.0266*** (0.00833)
GS- matches we randomly suggested			-0.000233 (0.00792)	-0.00527 (0.00661)
Controls: Firms' vacancy characteristics	No	No	Yes	Yes
Controls: Firm baselien characteristics	No	No	No	Yes
Observations	19,110	19,110	18,185	17,491
R-squared	0.003	0.003	0.005	0.007

Notes: We regress on worker- firm dyadic data for all workers and firms who were invited to the same job fair, whether the firm requested to meet that worker in person, using a centralized meeting-request system facilitated at the job fairs. We include controls for worker characteristics, firm characteristics, and vacancy characteristics (vacancies held by the firm in question at the time of the job fairs).

Appendix Table B.19: Heterogeneous effects: rm recruitment by baseline proportion of youth in workforce

	(1)	(2)	(3)	(4)	(5)
	Firm performed formal interviews (professionals)	Firm performed formal interviews (non-professionals)	Did any advertising for new hires	Did advertising for professional positions	Did advertising on the job boards
Proportion young high	0.0121 (0.0356)	-0.0501 (0.0568)	0.0545 (0.0461)	0.0492 (0.0558)	0.0846 (0.0607)
Proportion young low	0.0689 (0.0534)	0.0123 (0.0546)	0.0554 (0.0443)	0.177*** (0.0535)	0.0959 (0.0583)
Observations	473	473	473	473	473
R-squared	0.009	0.013	0.017	0.027	0.010
ControlMean 1	0.715	0.659	0.805	0.634	0.325
ControlMean 2	0.647	0.555	0.773	0.555	0.336
Test 1=0 (p)	0.462	0.430	0.989	0.0997	0.893

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets, corrected for the tests conducted within each panel.

Appendix Table B.20: Heterogeneous effects: firm recruitment by baseline use of formal recruitment methods

	(1)	(2)	(3)	(4)	(5)
	Firm performed formal interviews (professionals)	Firm performed formal interviews (non-professionals)	Did any advertising for new hires	Did advertising for professional positions	Did advertising on the job boards
Used formal methods	0.0666 (0.0473)	0.00436 (0.0486)	0.0781** (0.0393)	0.155*** (0.0475)	0.0827 (0.0517)
Did not use formal methods	-0.0159 (0.0661)	-0.0737 (0.0679)	-0.00102 (0.0550)	0.0309 (0.0664)	0.103 (0.0721)
Observations	473	473	473	473	473
R-squared	0.004	0.003	0.008	0.023	0.010
ControlMean 1	0.776	0.671	0.888	0.714	0.410
ControlMean 2	0.494	0.481	0.593	0.358	0.173
Test 1=0 (p)	0.311	0.350	0.242	0.128	0.816

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets, corrected for the tests conducted within each panel.

Appendix Table B.21: Heterogeneous effects: firm workforce composition at endline by proportion of workforce in professional occupations

	(1) Firm performed formal interviews (professionals)	(2) Firm performed formal interviews (non-professionals)	(3) Did any advertising for new hires	(4) Did advertising for professional positions	(5) Did advertising on the job boards
Proportion professional high	-0.0223 (0.0542)	-0.0331 (0.0557)	0.0573 (0.0452)	0.105* (0.0546)	0.0530 (0.0592)
Proportion professional low	0.100* (0.0544)	-0.0110 (0.0560)	0.0452 (0.0454)	0.121** (0.0549)	0.127** (0.0595)
Observations	473	473	473	473	473
R-squared	0.007	0.001	0.005	0.018	0.011
ControlMean 1	0.788	0.559	0.822	0.678	0.356
ControlMean 2	0.581	0.653	0.758	0.516	0.306
Test 1=0 (p)	0.111	0.780	0.849	0.829	0.380

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets, corrected for the tests conducted within each panel.

Appendix Table B.22: Heterogeneous effects: firm hiring after the fair by proportion of workforce in professional occupations

	(1) Num. new hires (professional)	(2) Num. new hires (non-prof)	(3) Most hires with degrees (professionals)	(4) Percentage new hires perm. positions (non-prof)	(5) Percentage new hires perm positions (prof)
Proportion professional high	-4.761 (3.825)	-17.89* (10.35)	-0.0815 (0.0580)	0.00427 (0.0402)	-0.0210 (0.0478)
Proportion professional low	0.422 (3.836)	1.430 (10.38)	0.0624 (0.0583)	-0.0214 (0.0447)	0.00920 (0.0409)
Observations	472	472	473	337	308
R-squared	0.003	0.006	0.007	0.001	0.001
ControlMean 1	20.51	62.43	0.669	0.840	0.892
ControlMean 2	3.444	27.85	0.484	0.958	0.864
Test 1=0 (p)	0.339	0.188	0.0800	0.669	0.633

Standard errors in parentheses

*** p<0.01, ** p<0.05, * p<0.1

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets, corrected for the tests conducted within each panel.

Appendix Table B.23: Heterogeneous effects: rm recruitment by proportion of workforce in professional occupations

	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
	Total number of employees	Prop. professional workers on perm. contract	Prop. non-prof workers on perm. contract	Av. starting salary (professionals)	Av. starting salary (non-prof's)	Prop. prof workers with degree	Prop. non-prof workers with degree	Average worker not under-qualified

Test 1=0 (p)	0.0641	0.454	0.528	0.442	0.646	0.612	0.163	0.435

Standard errors in parentheses
*** p<0.01, ** p<0.05, * p<0.1

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets, corrected for the tests conducted within each panel.

Appendix Figure B.2: Distribution of employer beliefs by education

Notes: Each panel shows the distribution of employer beliefs, for some specific job-seeker characteristic. Each panel shows a kernel density plot (with bandwidth chosen using Silverman's plug-in), then a box-plot (showing 5th, 25th, 50th, 75th and 95th percentiles), followed by a direct visualisation of data (with random vertical jitter). For each panel, we superimpose a vertical line at the true value of the statistic in our sample.

Appendix Figure B.3: Firms' beliefs about the distribution of job-seekers' reservation wages: Secondary-educated job-seekers

Notes: These figures show the distribution of firms' beliefs about job-seekers' reservation wages. In each graph, we show this at five wage points: in each case, we show the distribution of firms' beliefs (using thin bars to show the 10th and 90th percentiles, thick bars to show the 25th and 75th percentiles, and a star symbol to show the median). The coloured lines show the true proportion of our job-seekers with a given reservation wage (where the shaded area represents the 90% confidence interval for the proportion).

Appendix Figure B.4: Job-seekers' beliefs about the distribution of firm wages: Tertiary-educated job-seekers

Notes: These figures show the distribution of job-seeker beliefs about firms' wages. In each graph, we show this at five wage points: in each case, we show the distribution of job-seeker beliefs (using thin bars to show the 10th and 90th percentiles, thick bars to show the 25th and 75th percentiles, and a star symbol to show the median). The coloured lines show the true proportion of firms with a given wage (where the shaded area represents the 90% confidence interval for the proportion).
